## 1. TRIANGULAR ARRAY PRIME LINES

A prime number is a whole number greater than 1 which is not a product of any whole numbers greater than 1. What patterns, if any, are recognizable when prime numbers are singled out in an array where the whole numbers are listed in a triangular way such as the following?

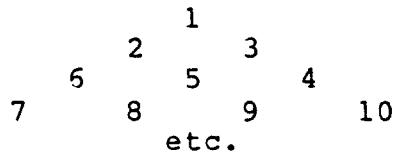

Figure 1.

This was a question I asked myself after being inspired by the cover of the March, 1964 issue of Scientific American to try my hand at finding interesting prime number patterns via new ways of listing the whole numbers. There were indeed patterns generated, and though I turned 14 that March, it was not until my sophomore year at the University of Southern California five years later that I recognized them.

Before I discuss the patterns I eventually saw, I wish to briefly explain why there was a five year delay before I did see them.

As I was preparing my original triangular array of numbers, I made the near-disastrous mistake of imposing patterns on the primes already singled out, in the following manner: I connected any two primes either vertically or horizontally one space apart:

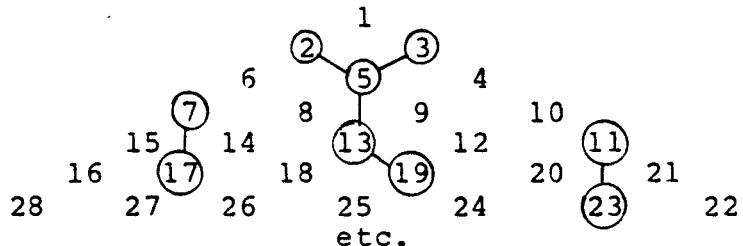

Figure 2.

I presumptuously called the random structures thus formed a "prime-stellar" relationship. What I meant was simply that each group of connected primes could be likened to star systems. (Most star systems have more than one sun, our solar system being an exception, having only one.) Actually, looking back, I guess I can't be blamed too severely for that approach (connecting neighboring primes) since the

scheme detailed in the "Mathematical Games" section of that March, 1964 issue of Scientific American did the same type of thing with the primes when the whole numbers were listed in a spiral thus:

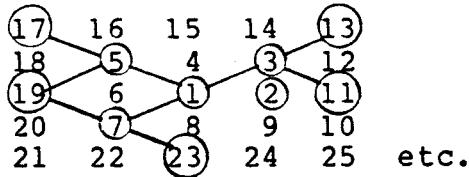

Figure 3.

At any rate, by the time I had placed the primes up to about the number 2,000 in my triangular array, the array was so cluttered with these extraneous "patterns" that I could no longer hope to see any real patterns there. (See figure 4.)

Indeed, it was not until I returned to the triangular array approach some five years later that I finally succeeded in merely completing the array before attempting pattern recognition.

This time my approach was richly rewarded. When the array of dots representing primes is turned at the proper angle and viewed on edge, lo and behold a series of parallel, straight, unbroken lines of primes leaps out at you! (See figures 5 and 6).

When the array is looked at similarly from the other side of the triangle, more lines appear. (See figure 7.)

When both sets of lines are taken together, all five such straight lines are evident. (See figure 8.)

I soon discovered a way to enhance this effect while at the same time consolidating the sets of patterns into a single set of parallel lines. This was accomplished by re-arranging the prime dots according to a slightly different counting scheme:

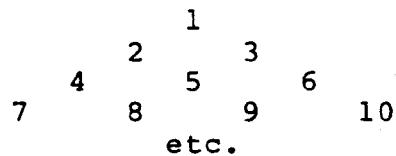

Figure 9.

(See figure 10.)

This form of the array eventually evolved into the cur-

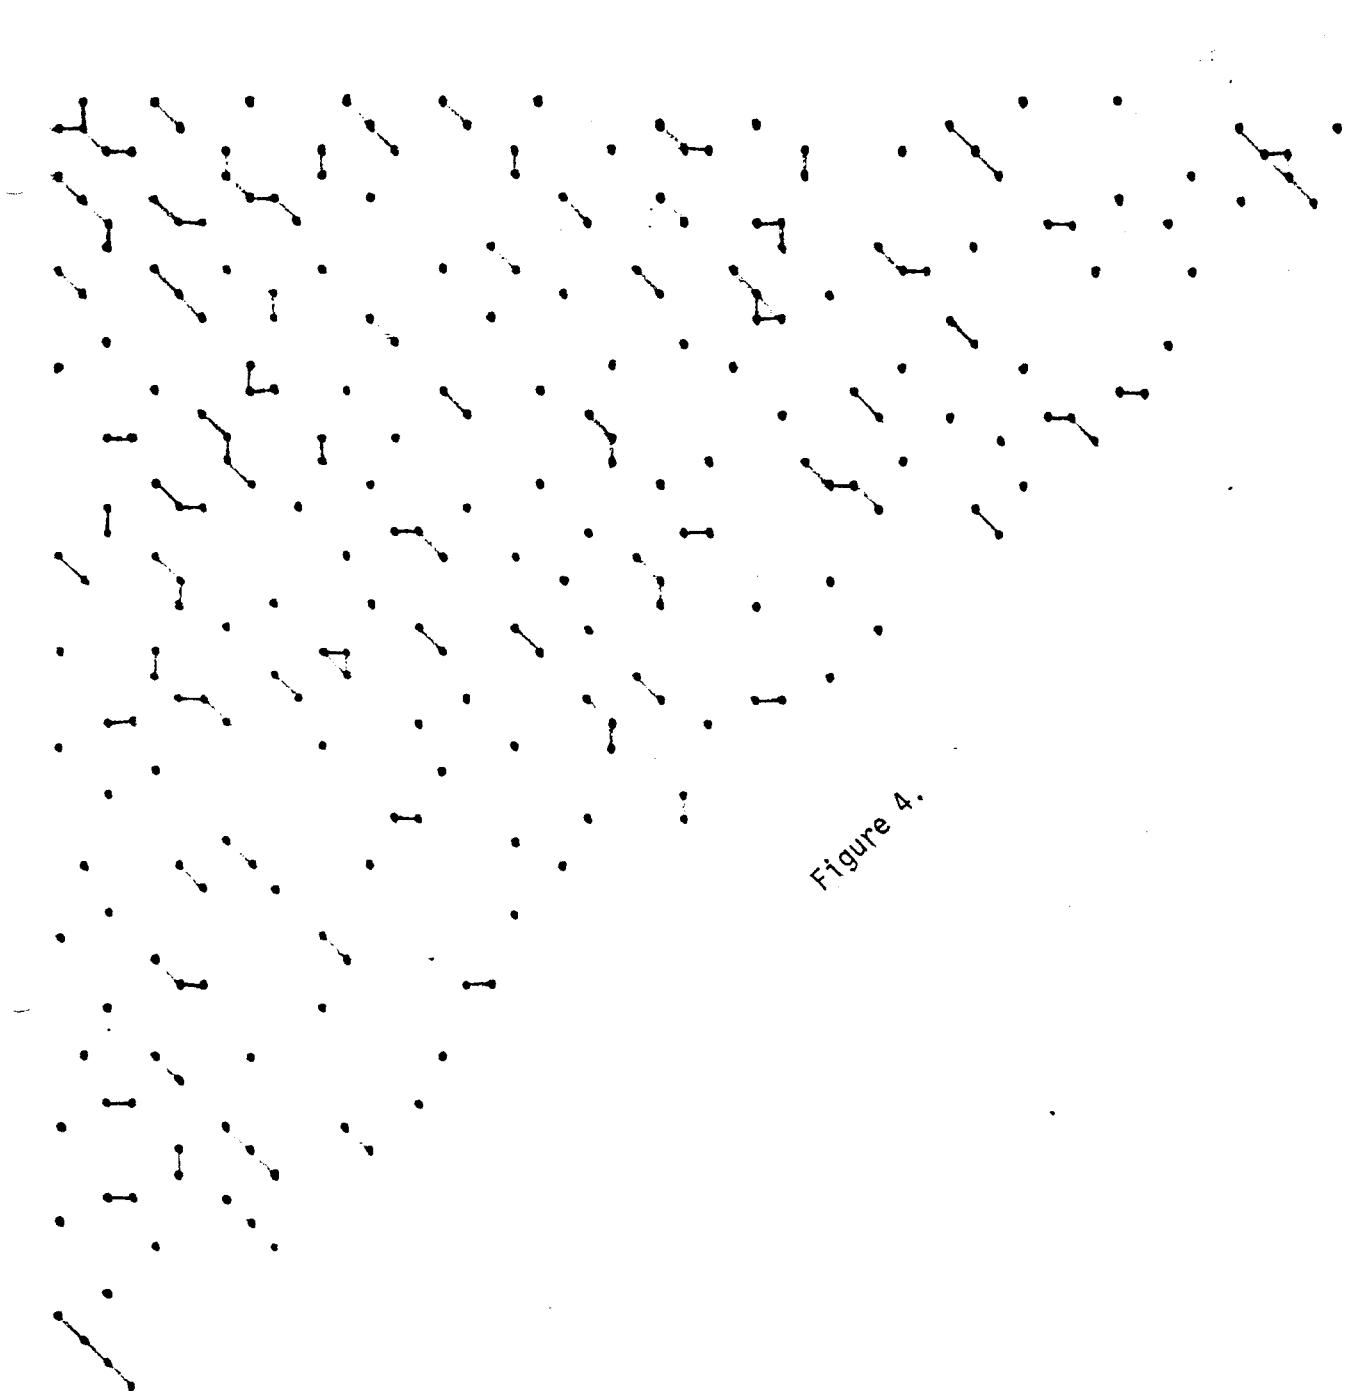

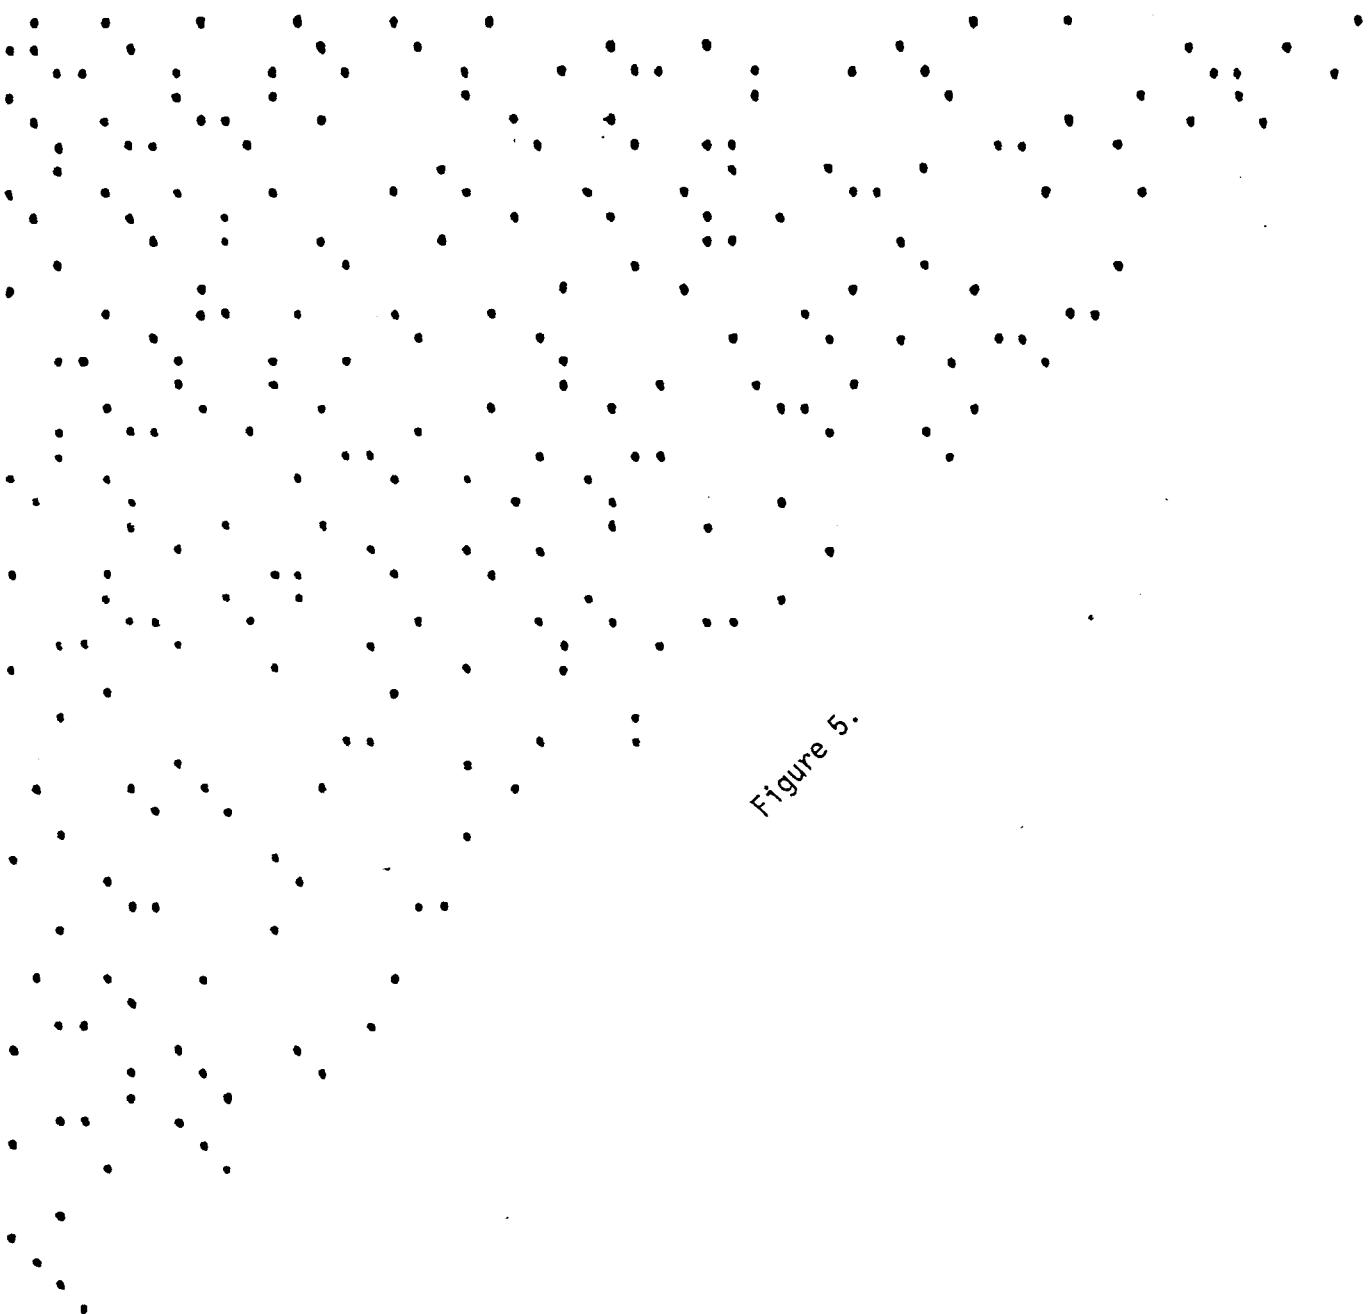

Figure 4.

Figure 5.

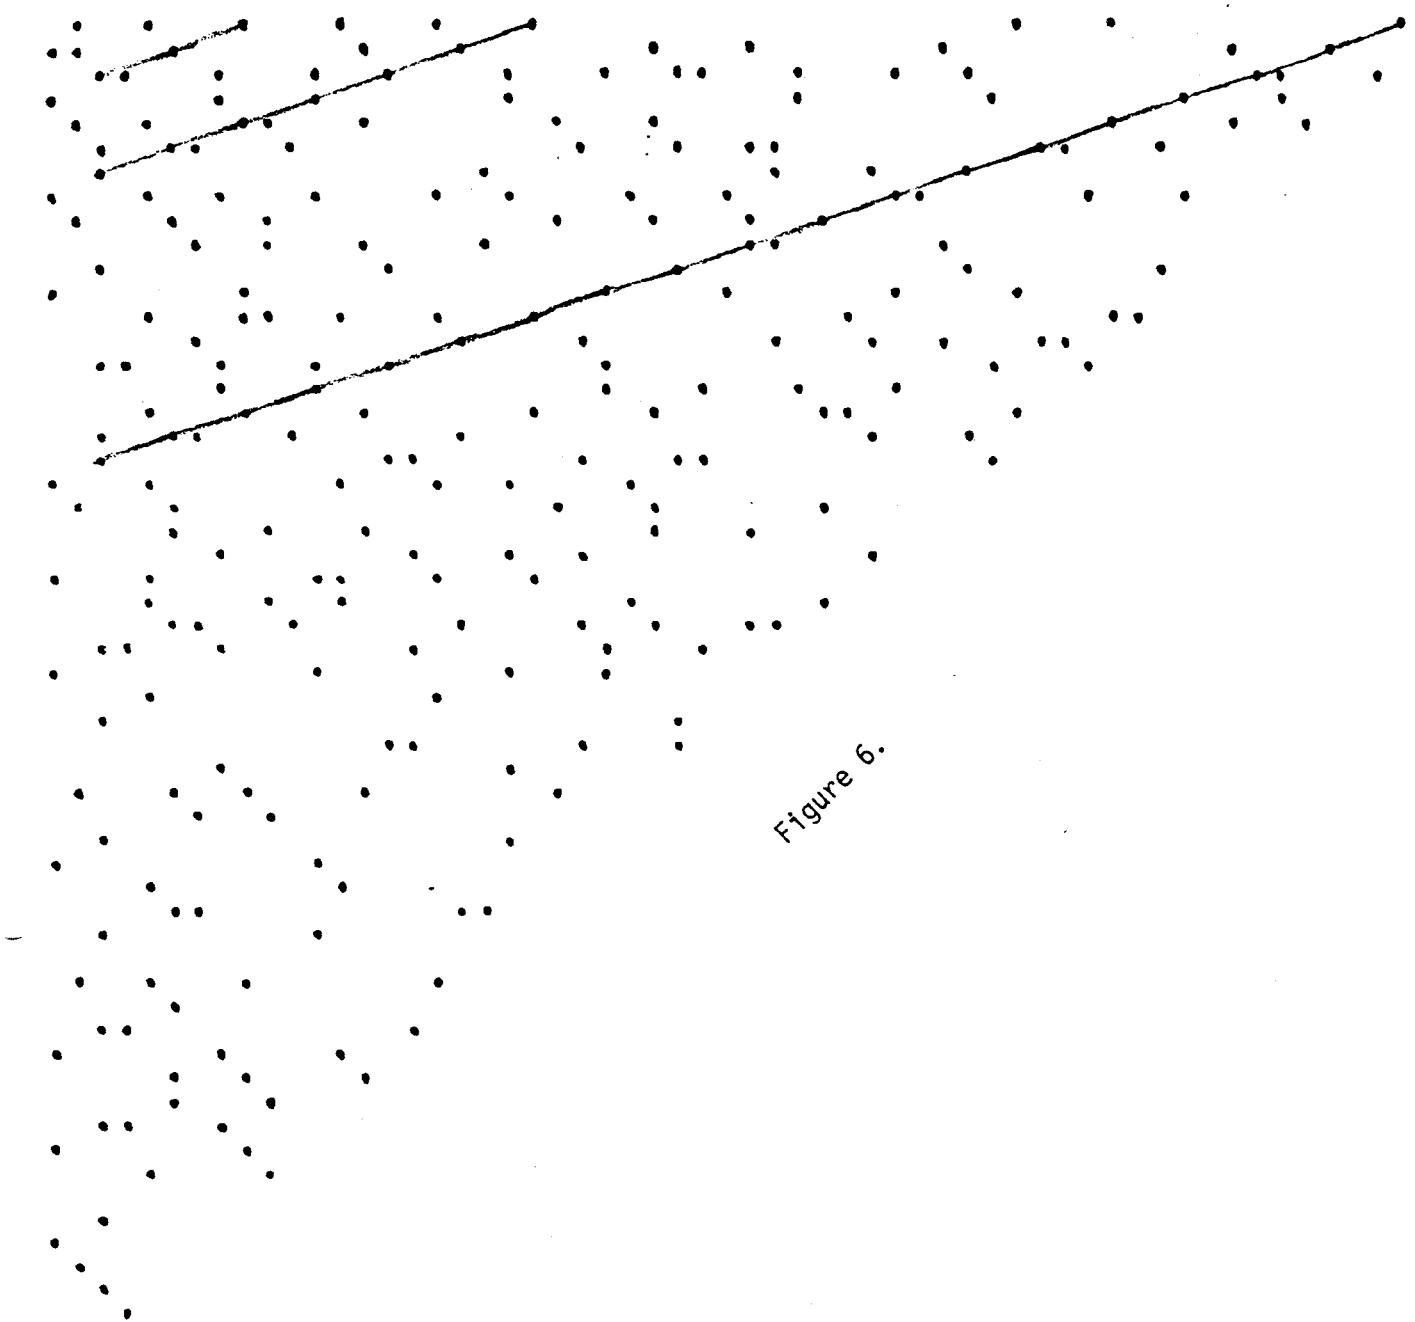

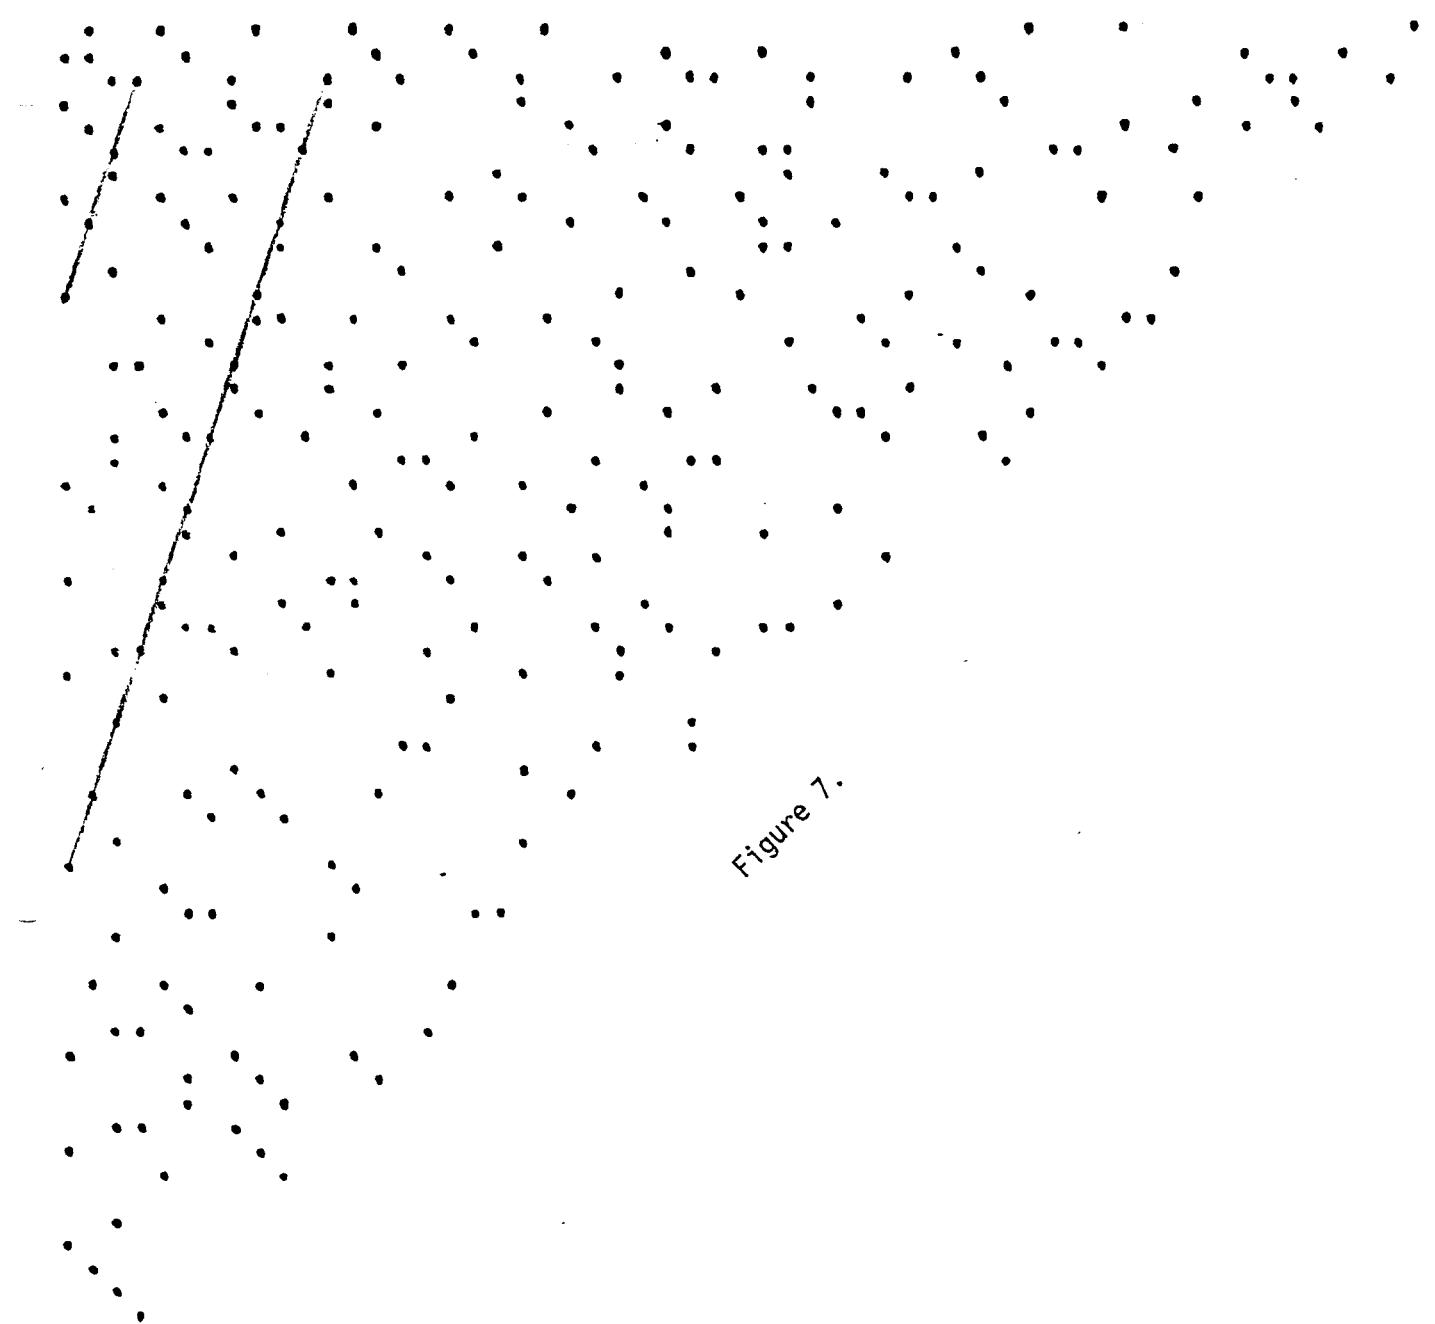

Figure 6.

Figure 7.

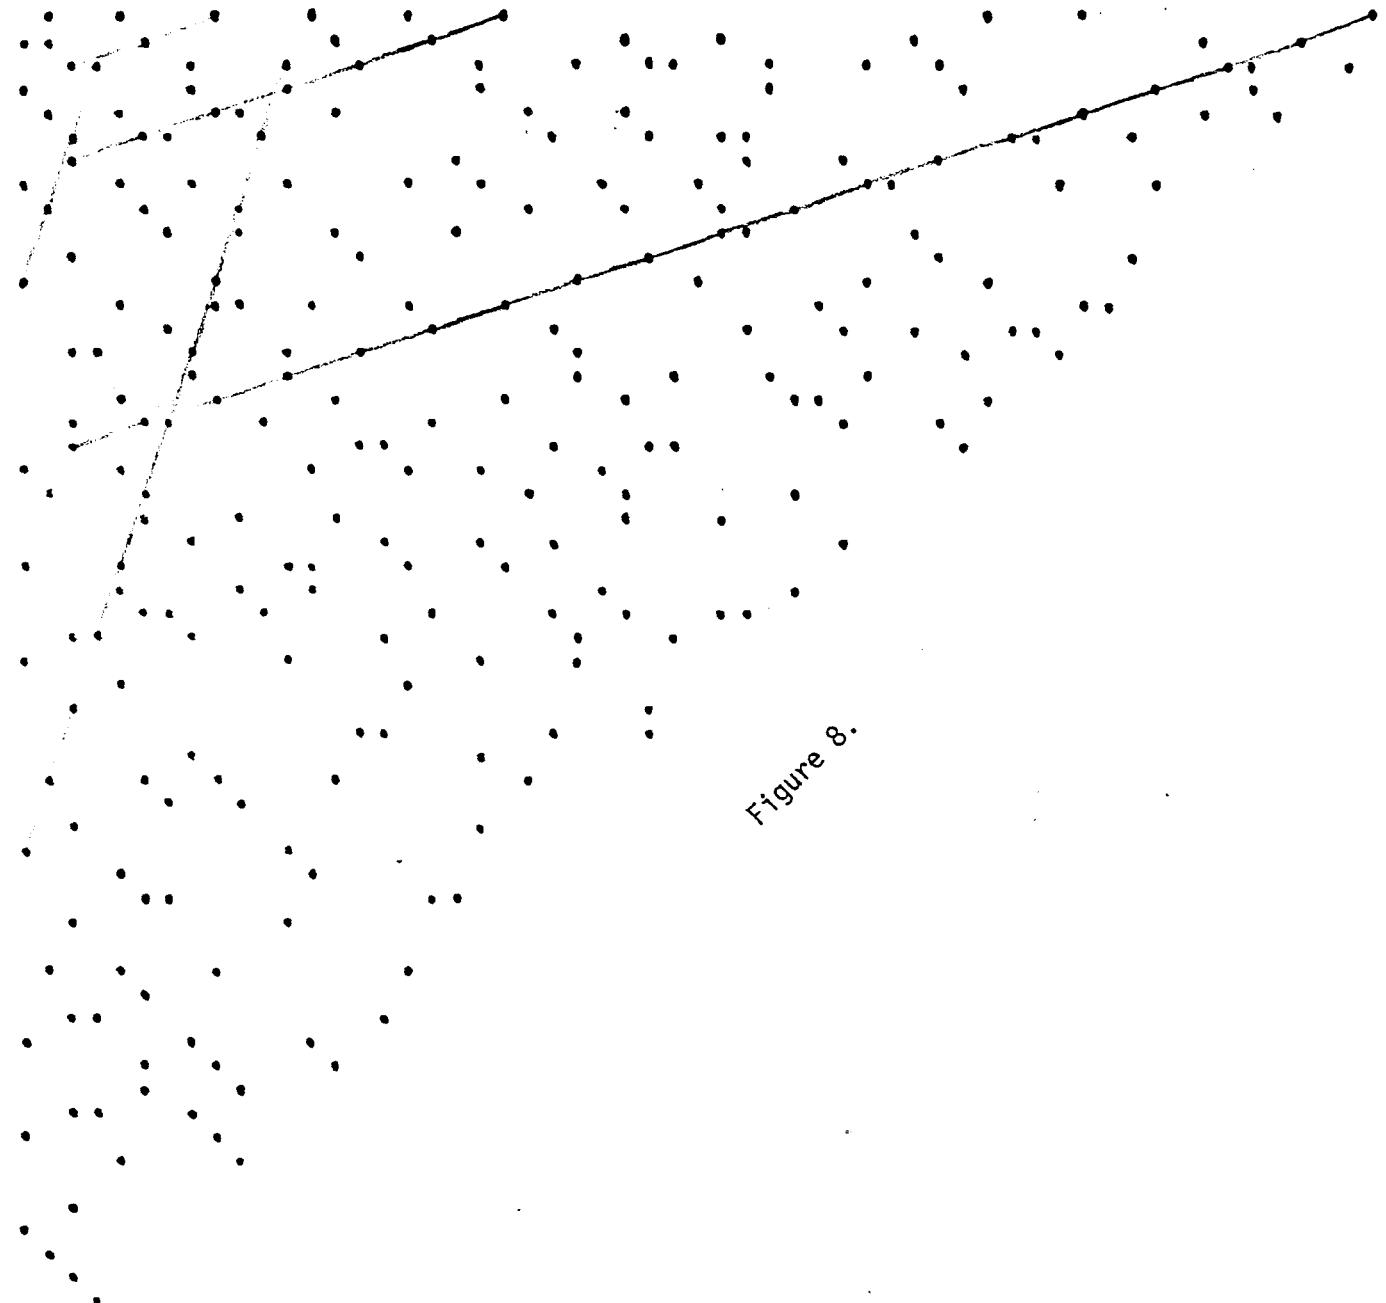

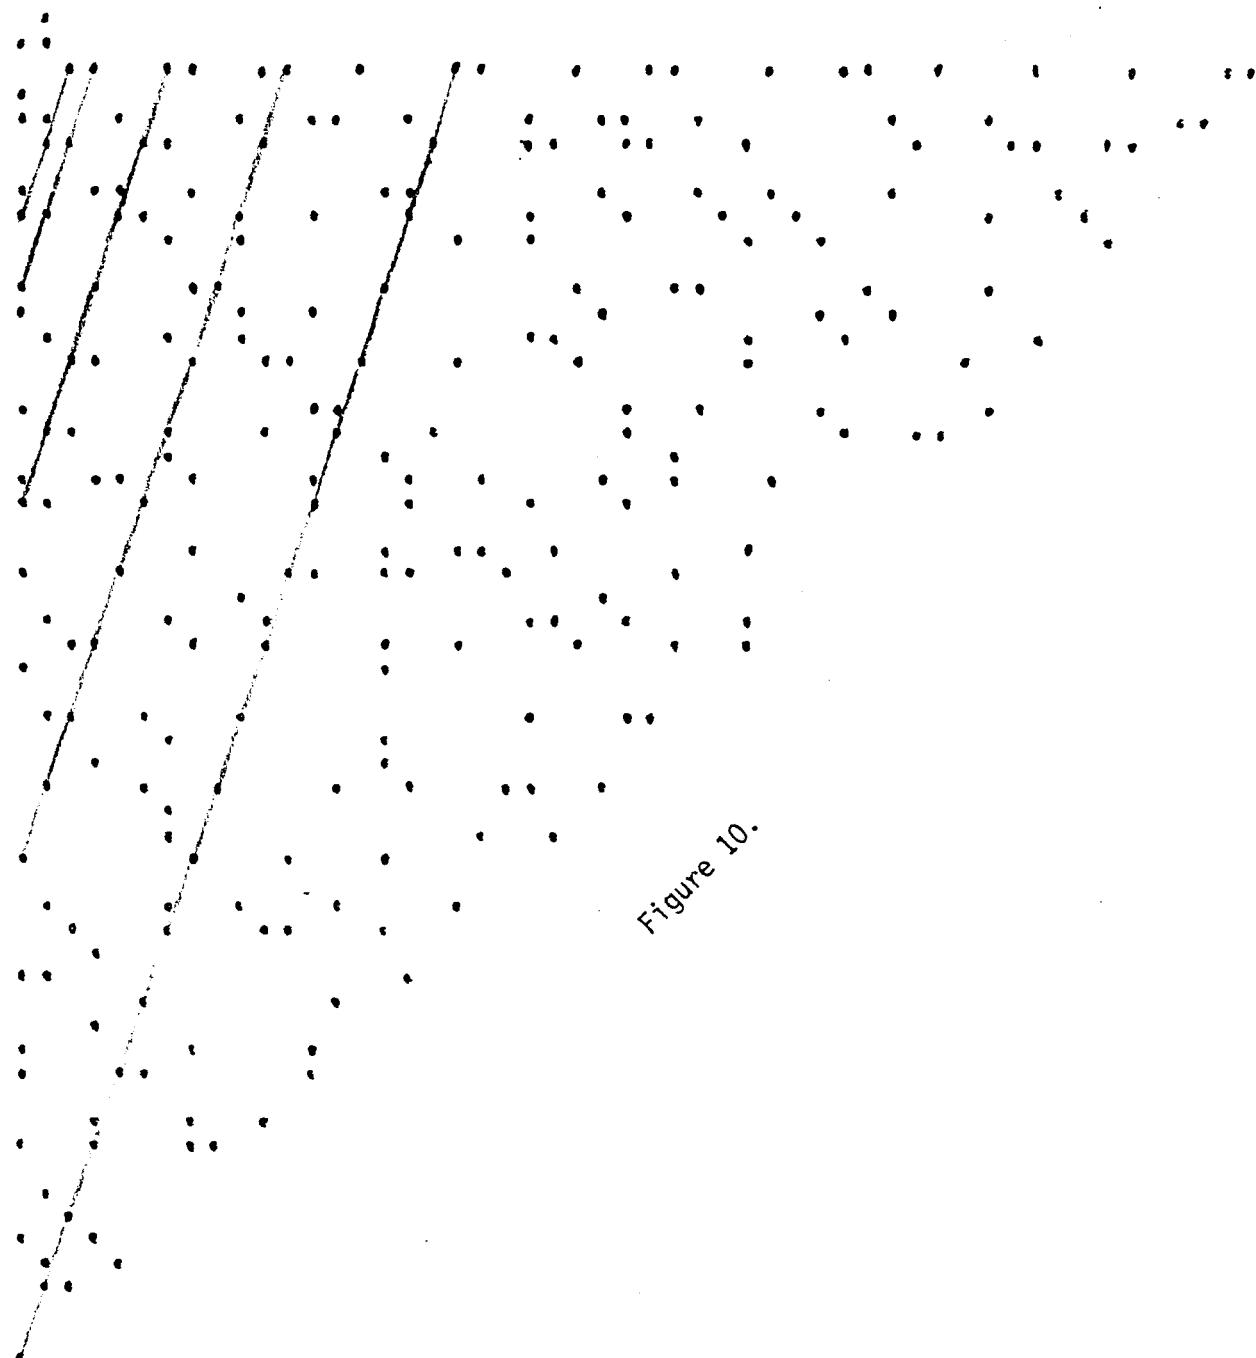

Figure 8.

rent "left-justified" form:

1			
2	3		
4	5	6	
7	8	9	10

etc.

Figure 11.

(See figure 12.)

## 2. THE FORMULAS FOR THE FIVE LINES

Now, what about these straight lines? What algebraic expressions generate them? Indeed, were they actual or had I somehow erred in placing my dots?

After verifying that each dot forming a link in those chains (so to speak) truly represents a prime number, I determined the expression generating each such chain. (See figure 13.)

As an aside, I might point out that the distances between the straight lines form a nice progression: 1, 3, 5, 7. (See figure 14.)

Do the expressions still yield primes for greater values of  $x$ ? What about for smaller values of  $x$ ?

While above the upper limits of  $x$  given in figure 13 the formulas only haphazardly produce primes, each expression yields a prime for every whole value of  $x$  down to zero from the earlier lower limits of  $x$ .

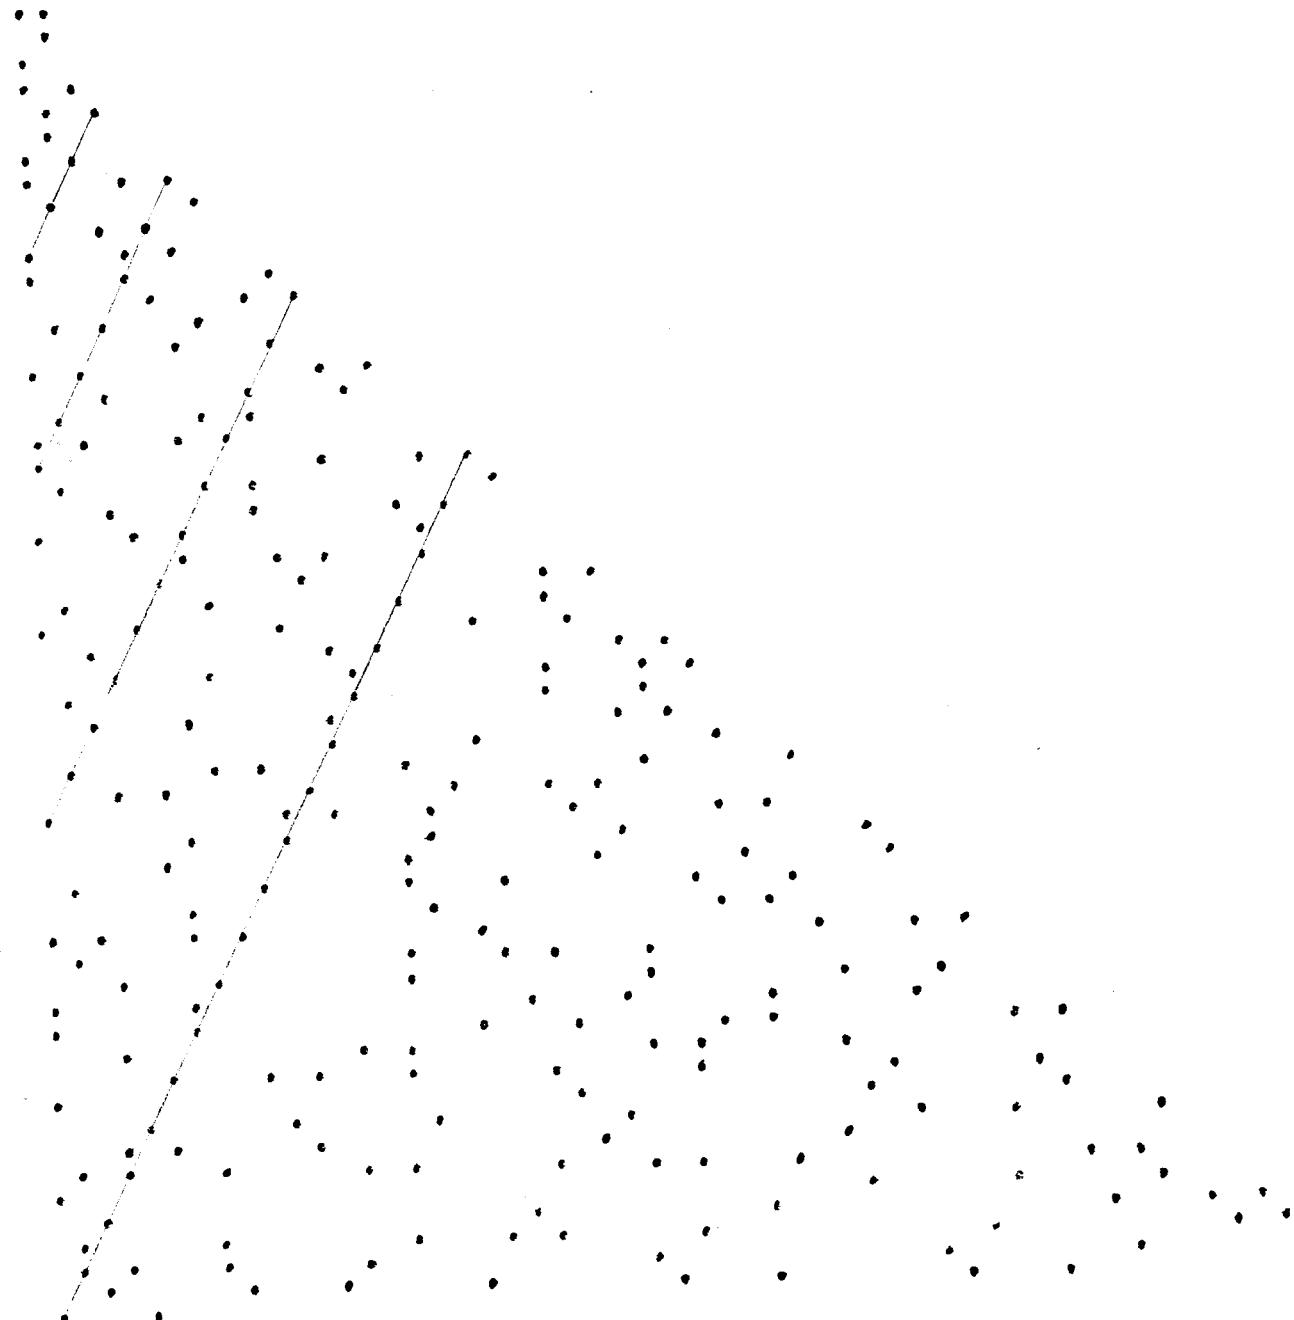

Figure 12.

$$2x^2 + 5 \quad 1 < x < 5$$

$$2x^2 + 2x + 7 \quad 1 < x < 6$$

$$2x^2 + 11 \quad 3 < x < 11$$

$$2x^2 + 2x + 19 \quad 5 < x < 18$$

$$2x^2 + 29 \quad 9 < x < 29$$

Figure 13.

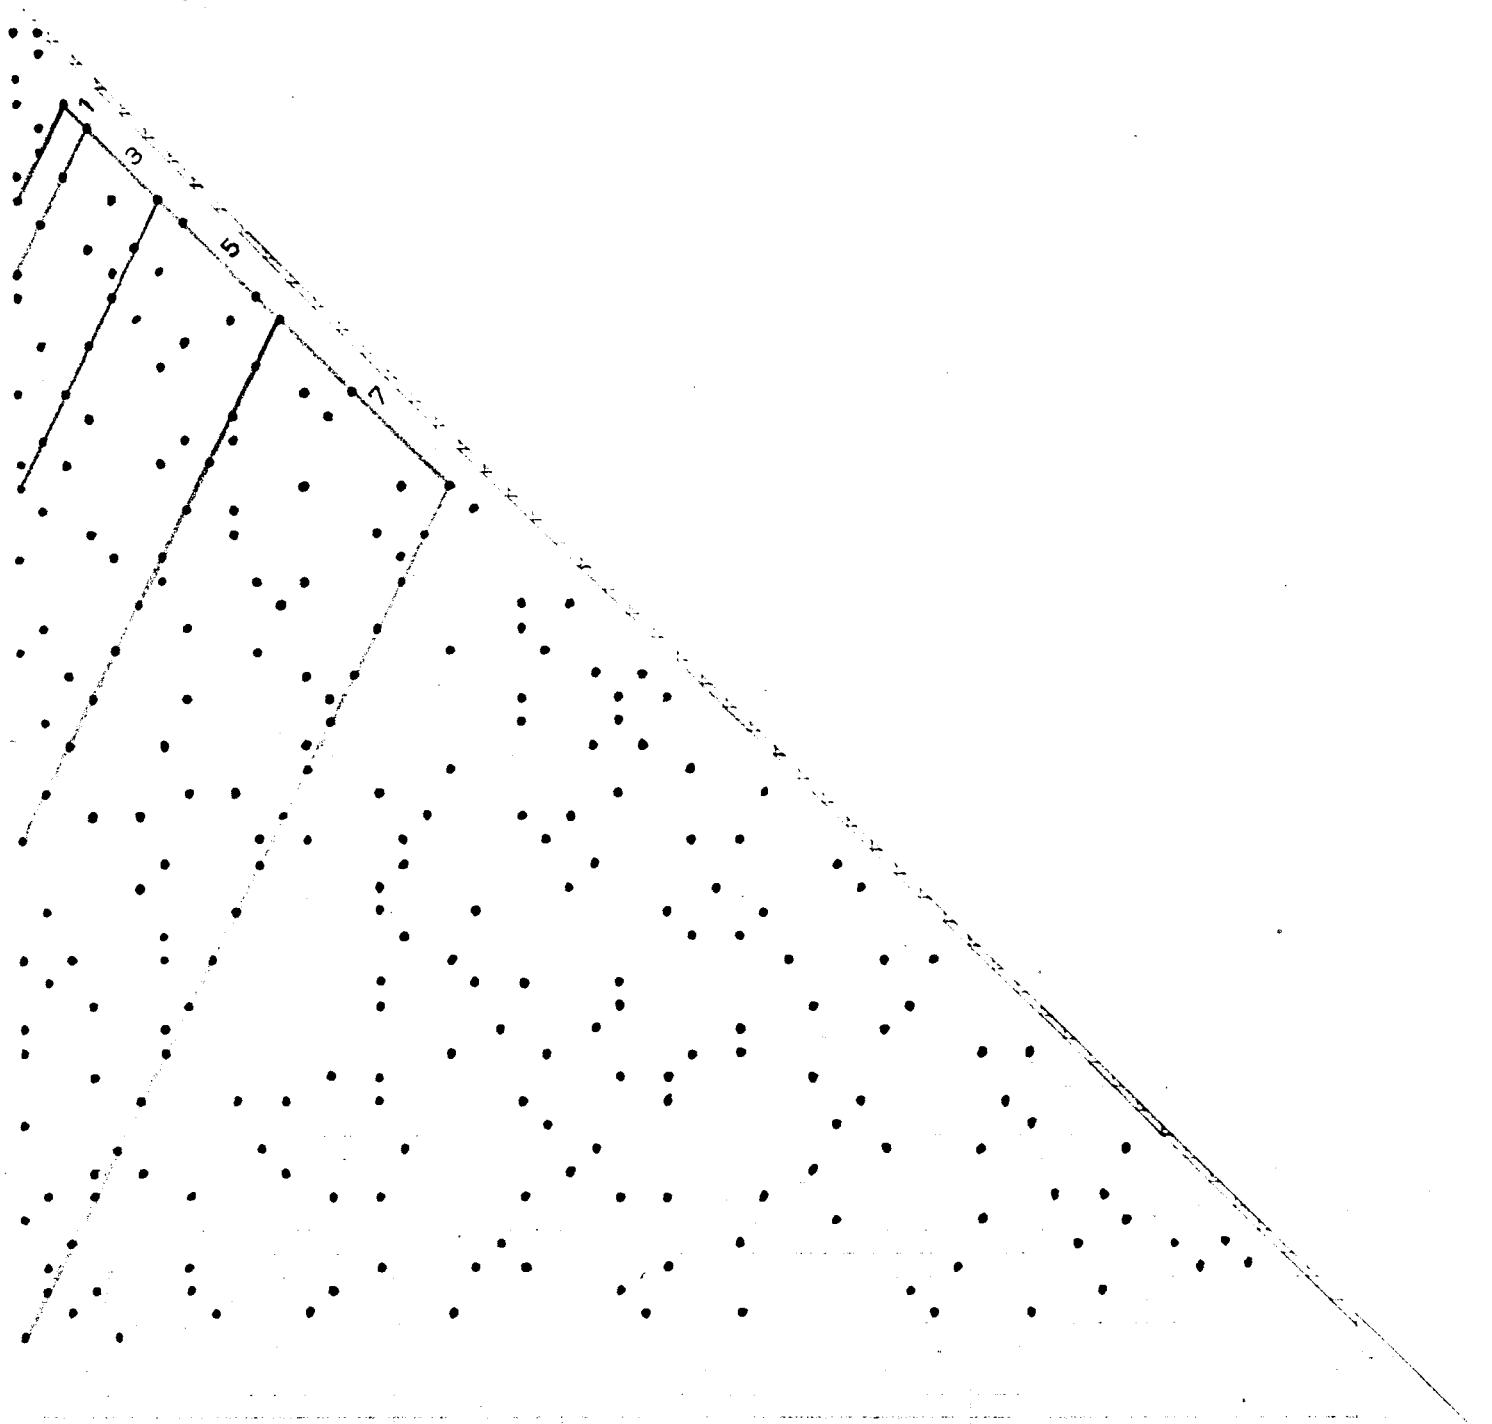

Figure 14.

Thus, the updated ranges for  $x$  are:

$$\text{for } 2x^2 + 5 \quad -1 < x < 5$$

$$\text{for } 2x^2 + 2x + 7 \quad -1 < x < 6$$

$$\text{for } 2x^2 + 11 \quad -1 < x < 11$$

$$\text{for } 2x^2 + 2x + 19 \quad -1 < x < 18$$

$$\text{for } 2x^2 + 29 \quad -1 < x < 29$$

$x$  whole.

Figure 15.

Since all of the prime sequences produced by these five formulas begin with nice small numbers, it was only natural to inspect the sequence of primes in general for any other simple sequences. And, sure enough, there are more simple sequences.

First I found one starting with 17: 17, 19, 23, 29, 37, 47, etc. up to 257. Then I found another, starting with 41: 41, 43, 47, 53, 61, 71, etc. up to 1601. This was by far the most remarkable sequence, holding true for forty consecutive values! The formula for this sequence is

$$x^2 + x + 41$$

while that for the sequence starting with 17 is

$$x^2 + x + 17.$$

Their valid ranges of  $x$  are:  $-1 < x < 40$  and  $-1 < x < 16$  respectively.

These two formulas bear a striking resemblance to certain of the original five formulas found from the triangular array, those of form  $2x^2 + 2x + c$  where  $c$  is a constant like 7 or 19. Perhaps the two new formulas, along with the initial five, formed part of some larger, all-embracing set of formulas?

I couldn't find any more  $x^2 + x + c$  type sequences for values of  $c$  higher than 41, but there are two more such se-

quences for values of c smaller than 17:

$$\begin{aligned} & x^2 + x + 5 \quad -1 < x < 4 \\ \text{and } & x^2 + x + 11 \quad -1 < x < 10. \end{aligned}$$

Figure 16.

### 3. THE FAMILY OF FORMULAS

I now had nine formulas. Listing them in order by their constant, I settled on the following arrangement:

$$\begin{aligned} & x^2 + x + 5 \\ & 2x^2 + 5 \\ & 2x^2 + 2x + 7 \\ & x^2 + x + 11 \\ & 2x^2 + 11 \\ & x^2 + x + 17 \\ & 2x^2 + 2x + 19 \\ & 2x^2 + 29 \\ & x^2 + x + 41. \end{aligned}$$

Figure 17.

There is a fascinating aspect to this list -- the formats of the formulas themselves form a pattern:

$$x^2 + x + c$$

$$2x^2 + c$$

$$2x^2 + 2x + c$$

$$x^2 + x + c$$

$$2x^2 + c$$

$$x^2 + x + c$$

$$2x^2 + 2x + c$$

$$2x^2 + c$$

$$x^2 + x + c.$$

Figure 18.

There is perfect symmetry of form stemming in both directions from the middle formula towards the first and last formulas, respectively. There is a formula of form  $x^2 + x + c$  at both ends of the list. The other two  $x^2 + x + c$  formulas are the fourth formula in from their respective ends of the list. Besides the  $2x^2 + c$  type of formula at the center of the list, the other two of that type are each the second from their respective ends of the list. Finally, the two  $2x^2 + 2x + c$  type formulas are respectively the third formula in from their ends of the list. Thus the list

can be represented in form by the following symmetrical list:

A  
B  
C  
A  
B  
A  
C  
B  
A.

Figure 19.

It is this symmetry, this inherent self-containment, that leads me to conjecture that my nine formula family may contain all such formulas in existence. I might add that there are no signs of any more unbroken lines of primes when the triangular array is extended down to 133 rows (down to about the number 9,000). (See figure 20.)

It was at this point in time, 1969, that I contacted a professor specializing in number theory, a Dr. Whiteman at U. S. C., and reported my findings over the phone. He was delighted, but he somewhat tarnished my pride of discovery by revealing that  $x^2 + x + 41$  was well-known and that the mathematician Euler had extensively studied "prime-rich" formulas 200 years earlier. (While writing this paper I decided to try to look up just what Euler had known. I visited the Fine Mathematics Library at Princeton University and looked up everything I could find on Euler. There was very little written in English, and nothing even remotely resembled "my" nine formulas. I then resorted to the painful task of scanning Euler's collected works -- running over twenty thick volumes -- for any sign of the formulas. The reason that that scanning was painful was that none of the writings are in English -- most are in Latin, some are in French, and some bits are in Euler's native German. I could find nothing relevant though there were chapters dealing with prime number theory. I suppose I just didn't hit the right spots.)

Subsequent to my conversation with Dr. Whiteman I sheepishly discovered that not only is  $x^2 + x + 41$  mentioned in many written discussions of primes, but in addition both it and  $x^2 + x + 17$  are cited even in the very article in that March, 1964 issue of Scientific American that had launched me on this involved quest.

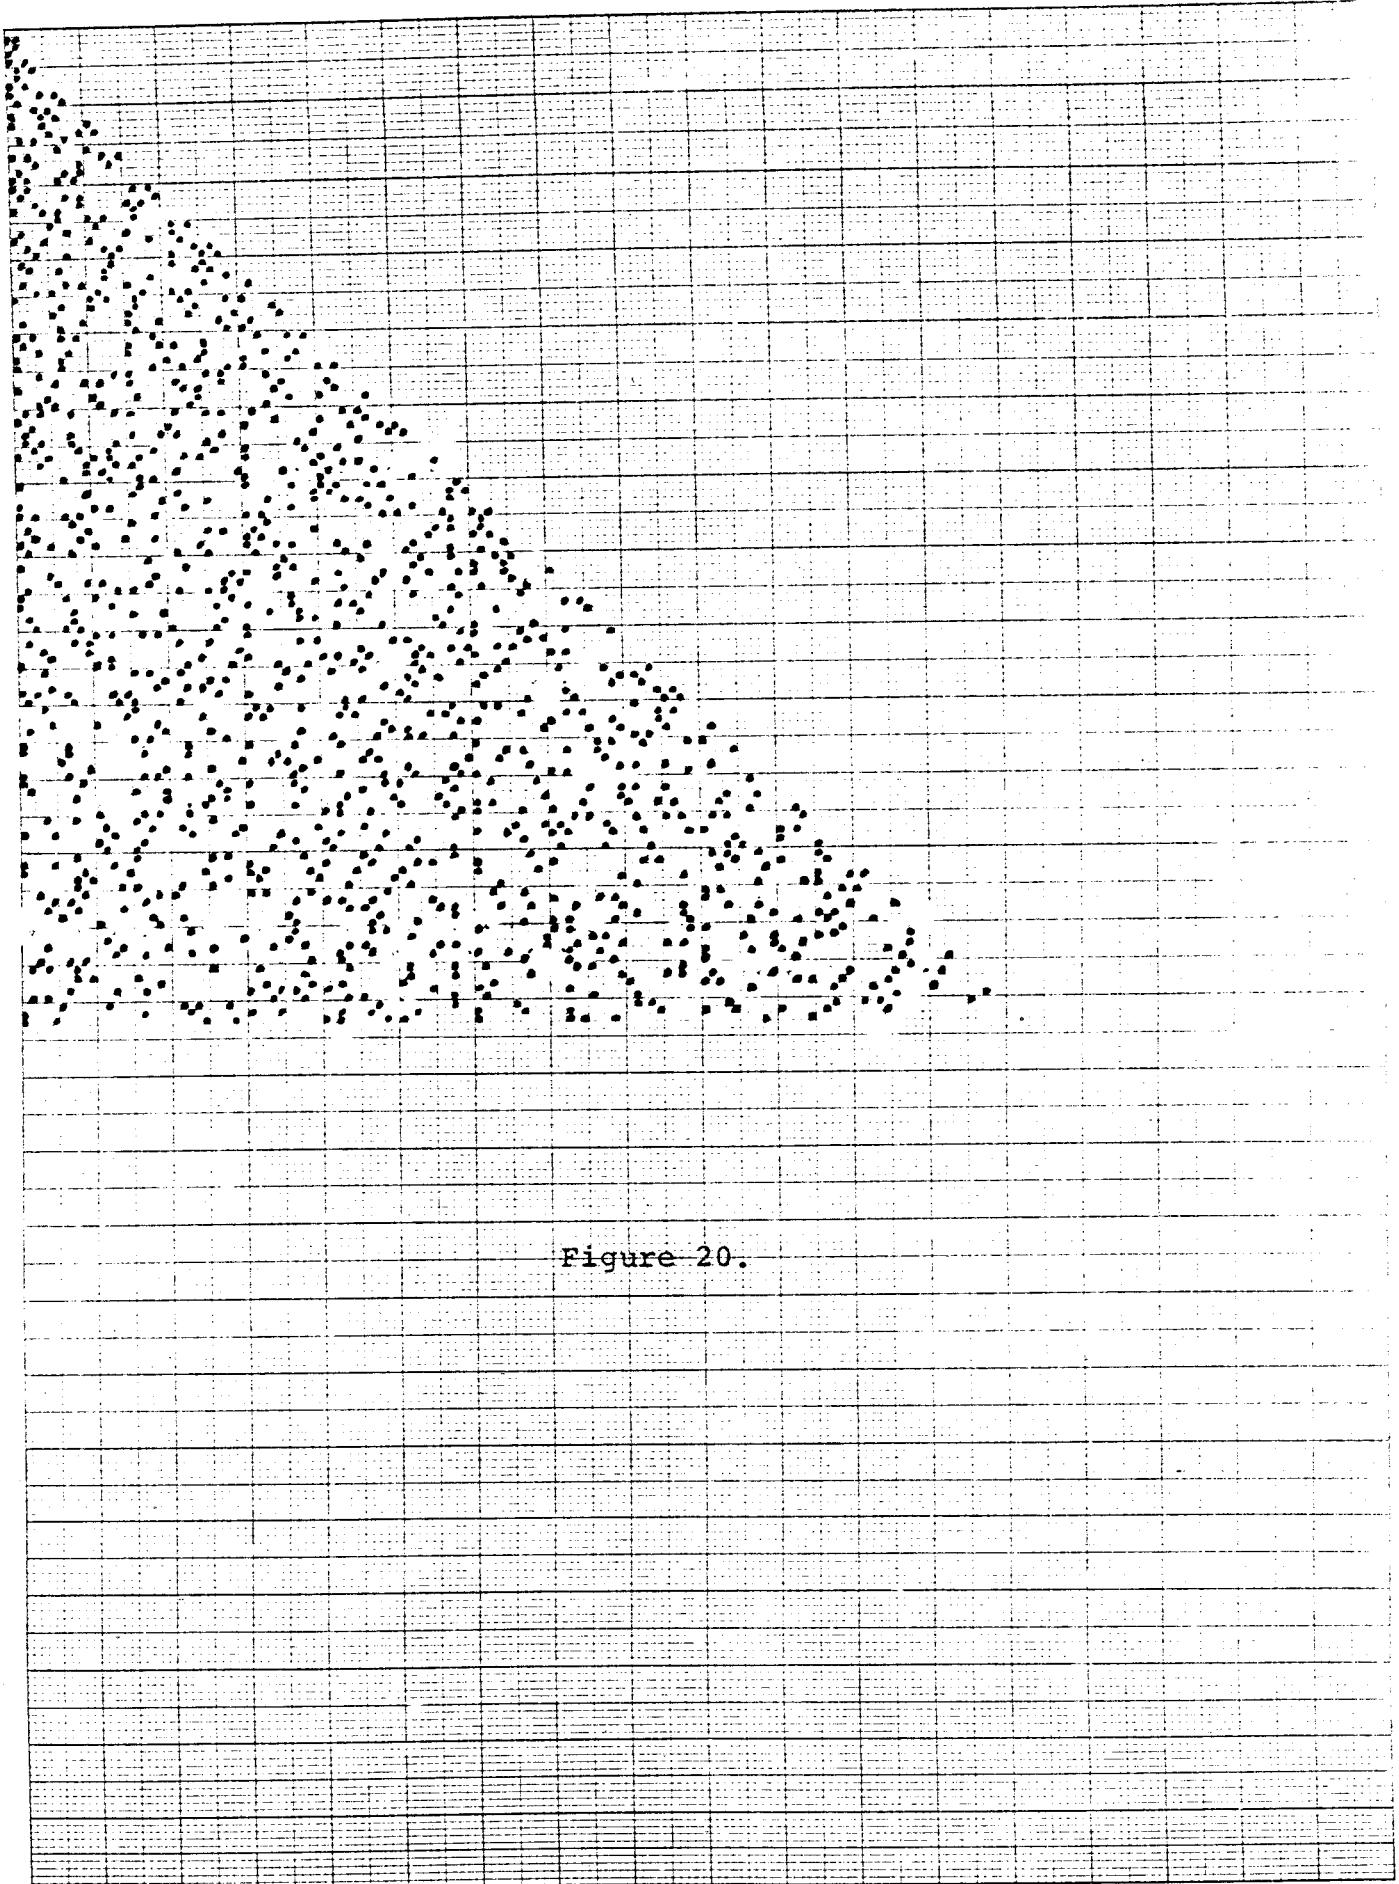

Figure 20.

## 2 4. $x^2 + x + 41$ ON THE TRIANGULAR ARRAY

Undaunted, I continued my studies of primes and patterns. I asked myself what  $x^2 + x + 41$  would look like plotted on the triangular array. Since it wasn't a straight line, what would it be? (See figure 21.) As you can see, the dots of  $x^2 + x + 41$  do tend to form fragments of curves.

### 5. EXTENSION OUT OF THE TRIANGLE

I decided to extend those curve fragments outside the boundary of the "hypotenuse" of the triangular array (See figure 22.) -- wow!

Each dot now seemed to be a member of several different curves, each curve going in a different direction. And, there seemed to be some kind of convergence point at the top center of the graph, where all the curves come together. It was this convergence effect that was to shortly lead me to explore this snail-shell shaped set of curves beyond even these confines. But before checking, I first wanted to know what  $x^2 + x + 17$  would do on the triangular array.

It turned out that  $x^2 + x + 17$  produces the exact same curves, only displaced to the right from the left edge of the graph by 17 positions instead of 41. It was an easy step from there to realizing that I could shift the convergence point all the way to the left edge of the graph by eliminating the constant altogether from  $x^2 + x + c$  (since  $c$  dictates the amount of displacement to the right from the left edge of the graph). So, just plain  $x^2 + x$  would produce the dazzling dot curves.

### 6. "THE DESIGN"

The next step was to extend the curves above the top of the graph and see just what the convergence point looked like from all sides. (See figure 23.) PHEW!

### 7. THE CURVE FAMILIES AROUND THE AXIS OF SYMMETRY

Looking at "the design" with the void at the bottom there is an obvious left and right symmetry. Further, there appear to be distinct families of curves composed of the dots of "the design". For example, extending from the vertex of the void straight upward is one family of narrow, nested, downward curving curves. (See figure 24.)

Then one can see both immediately to the left and right of that central family two slightly wider downward curving curve families. (See figure 25.)

Then, at the far left and right edges of "the design" are two broad downward curving curve families. (See figure 26.)

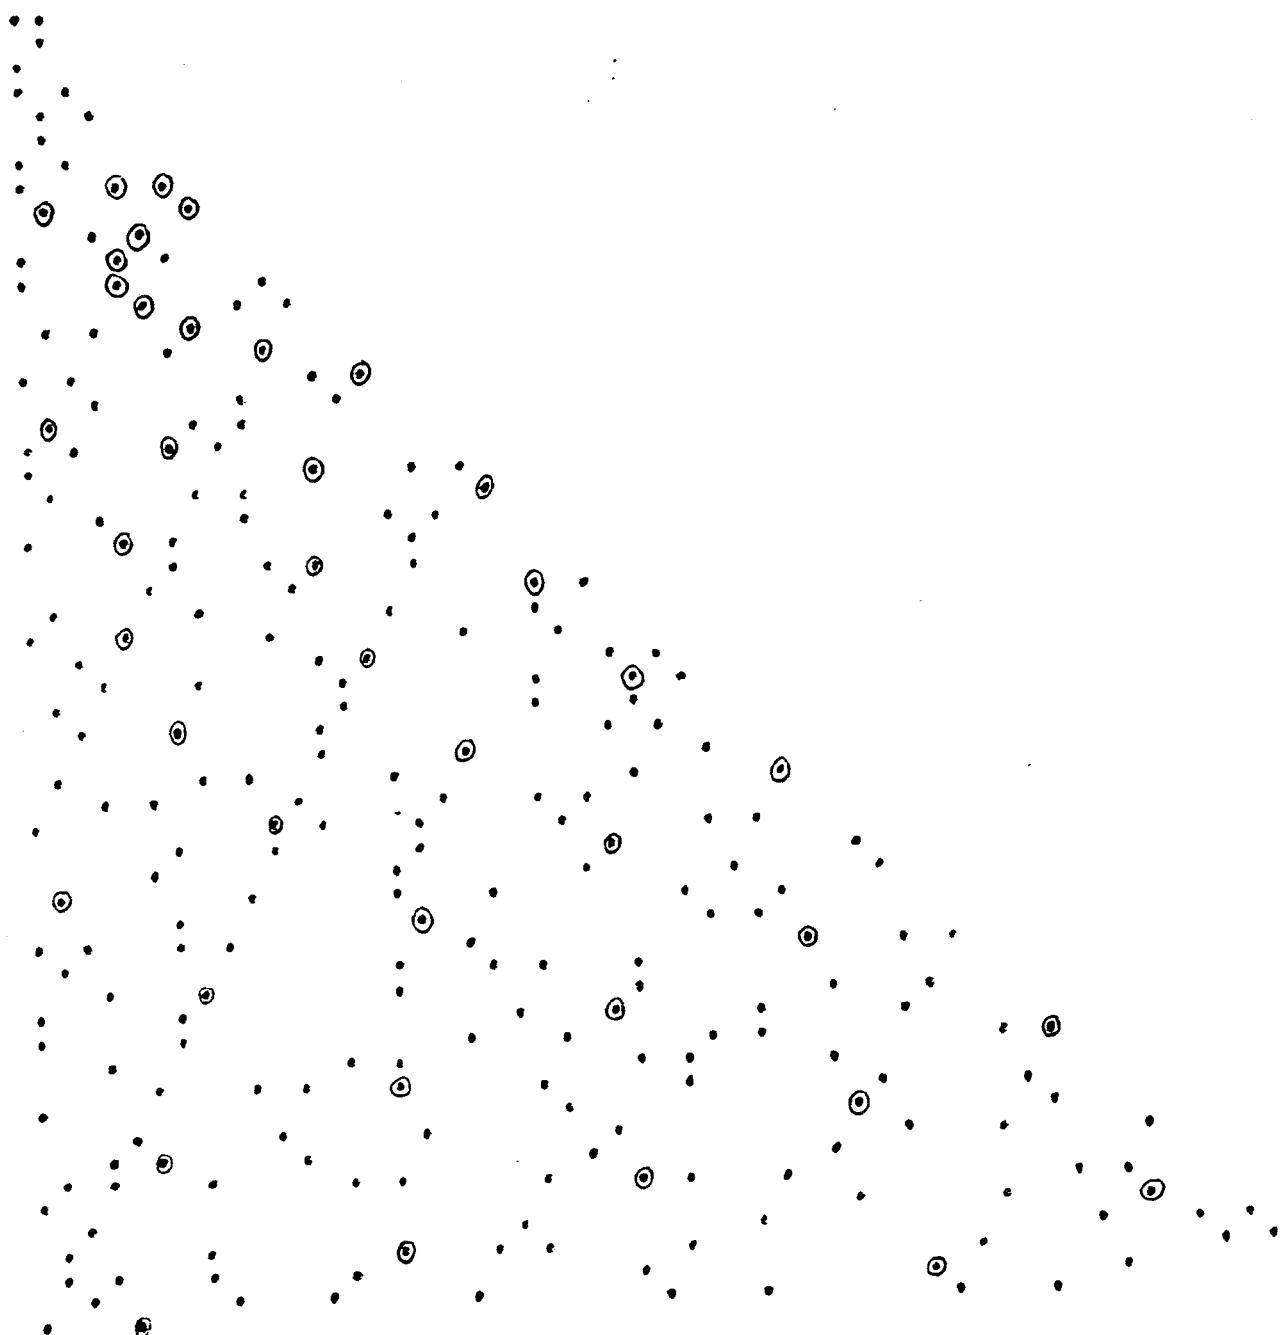

Figure 21.

Figure 22.

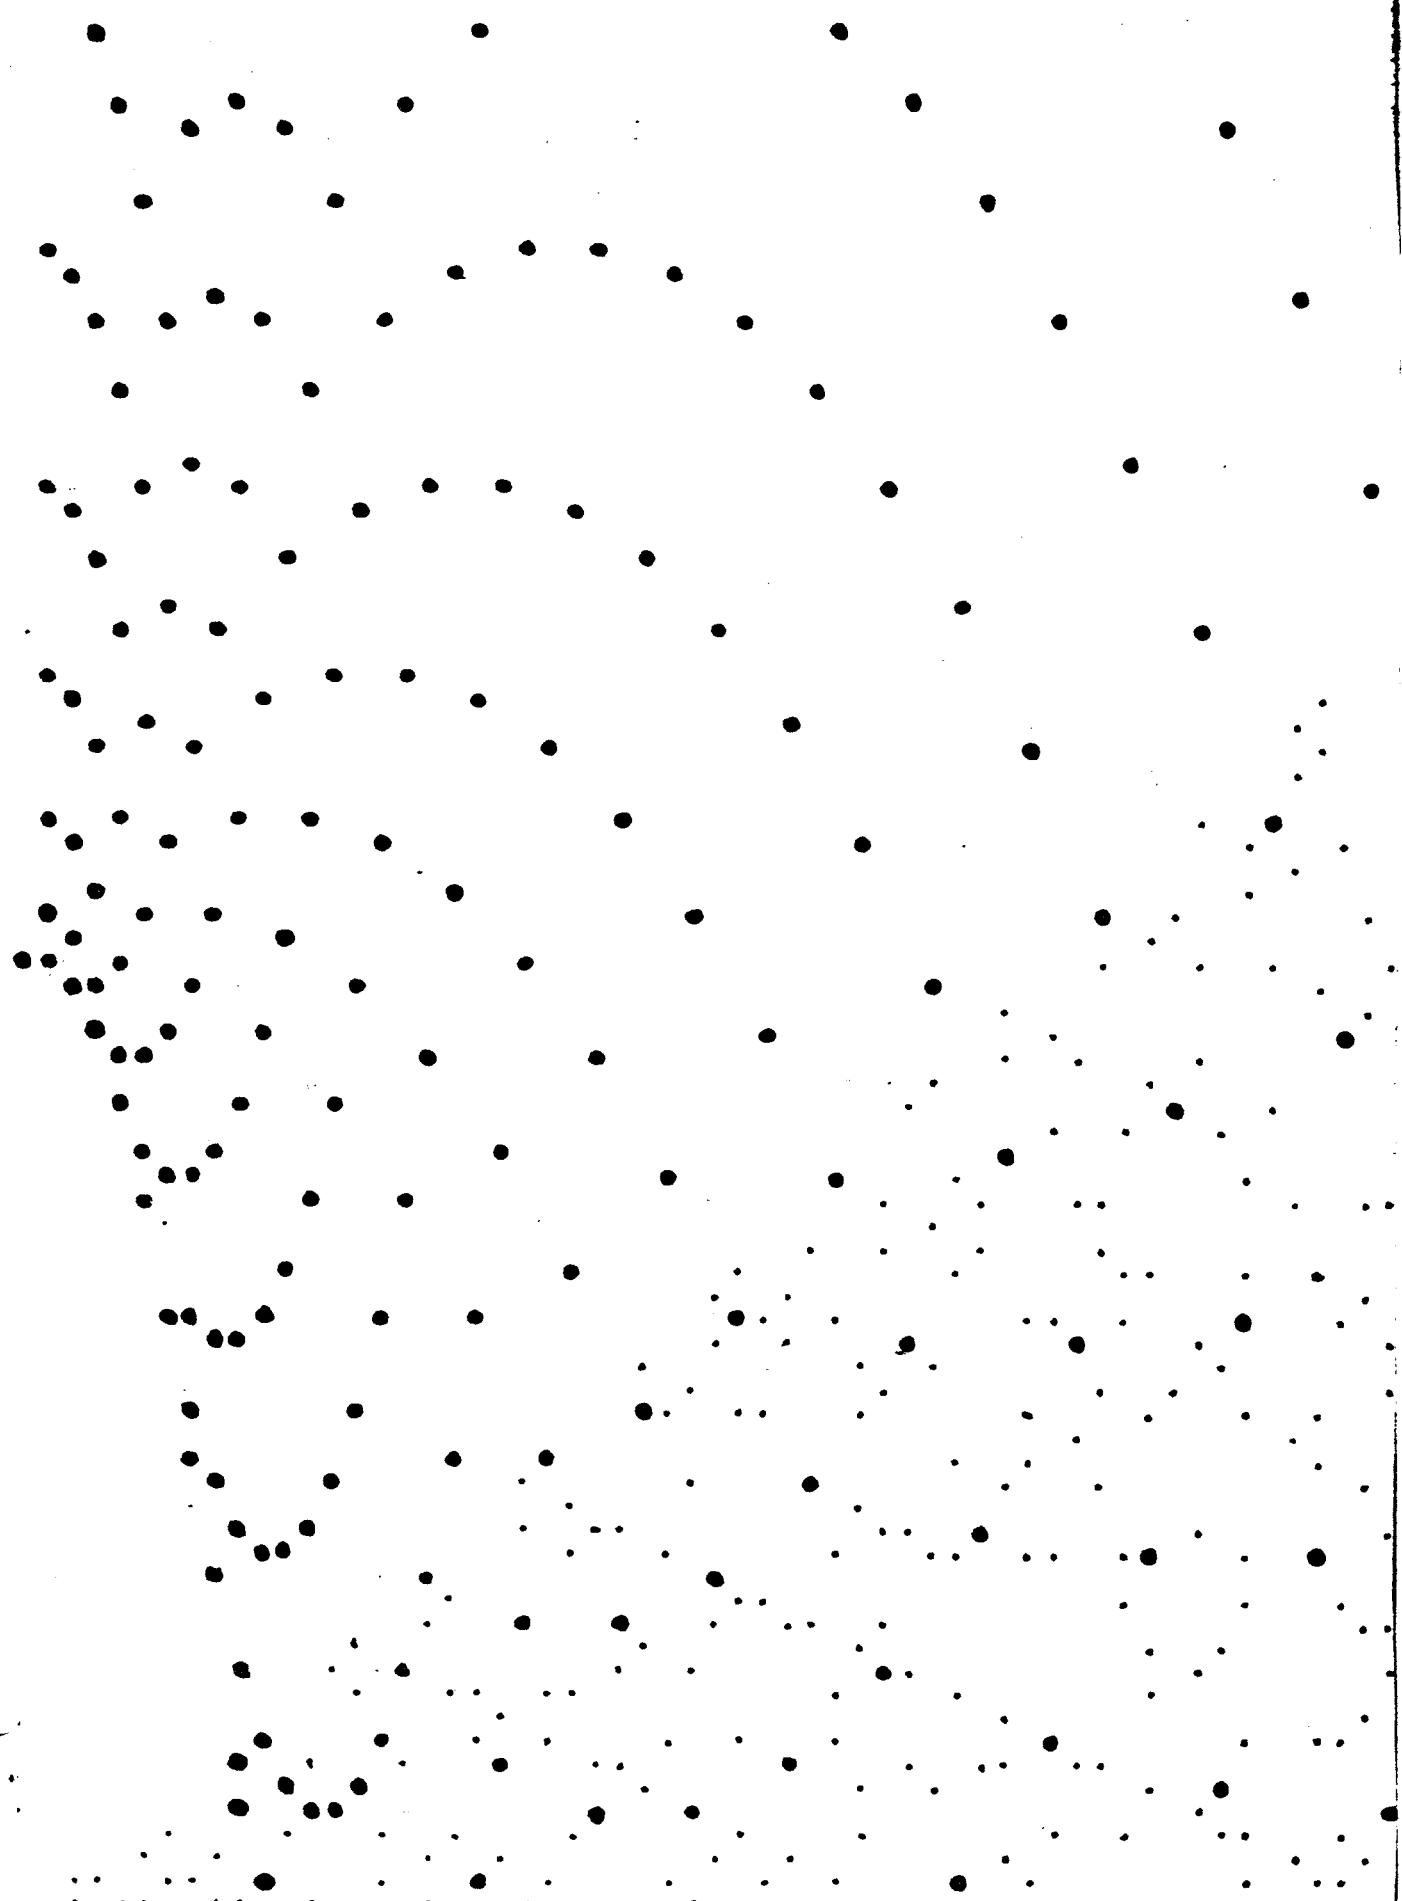

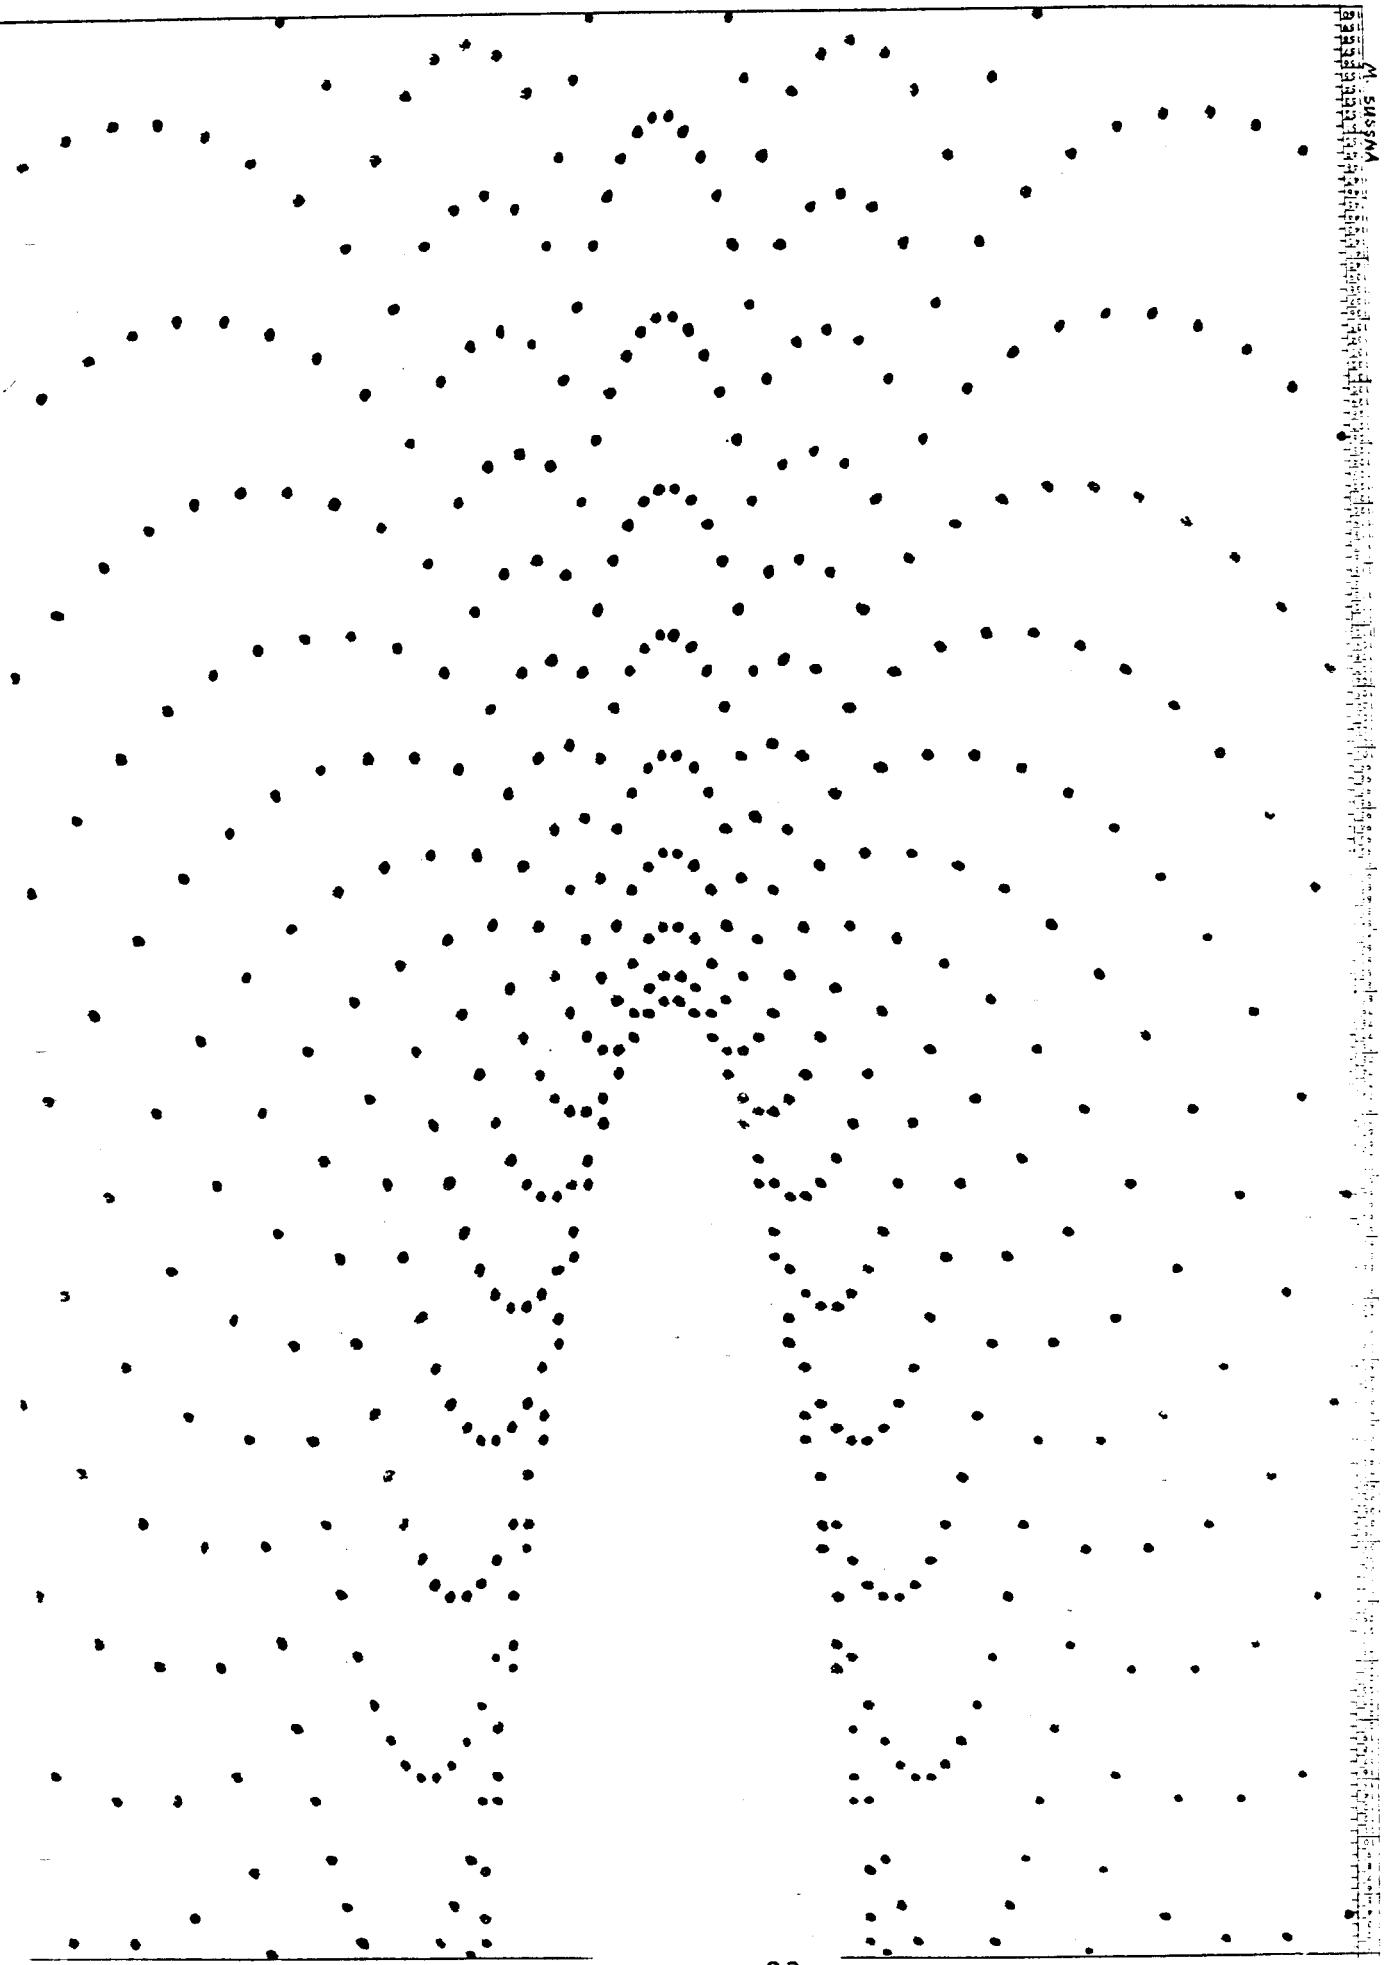

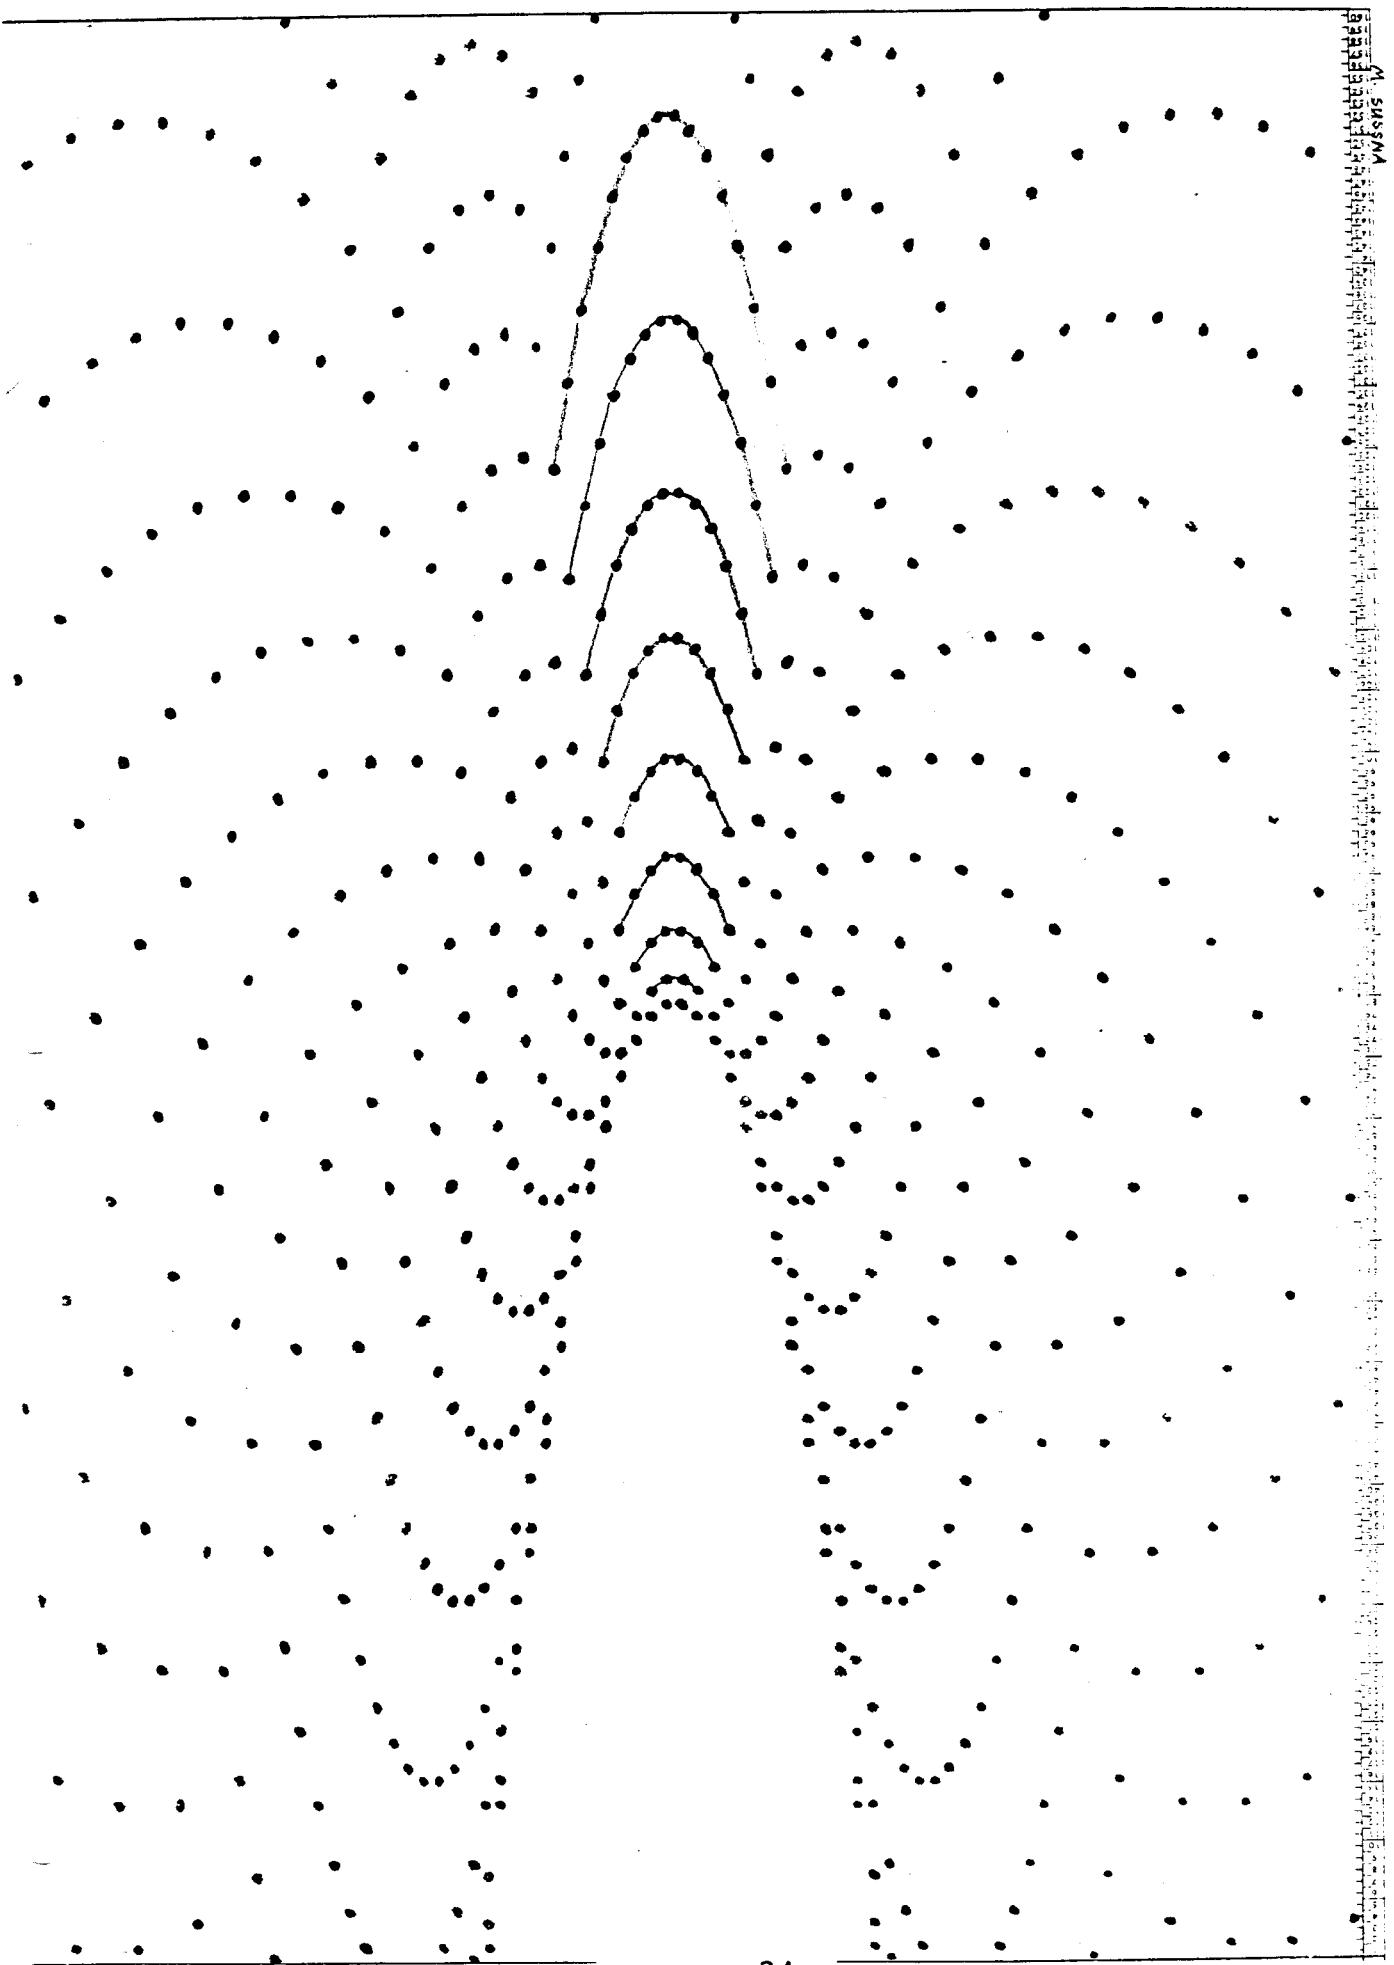

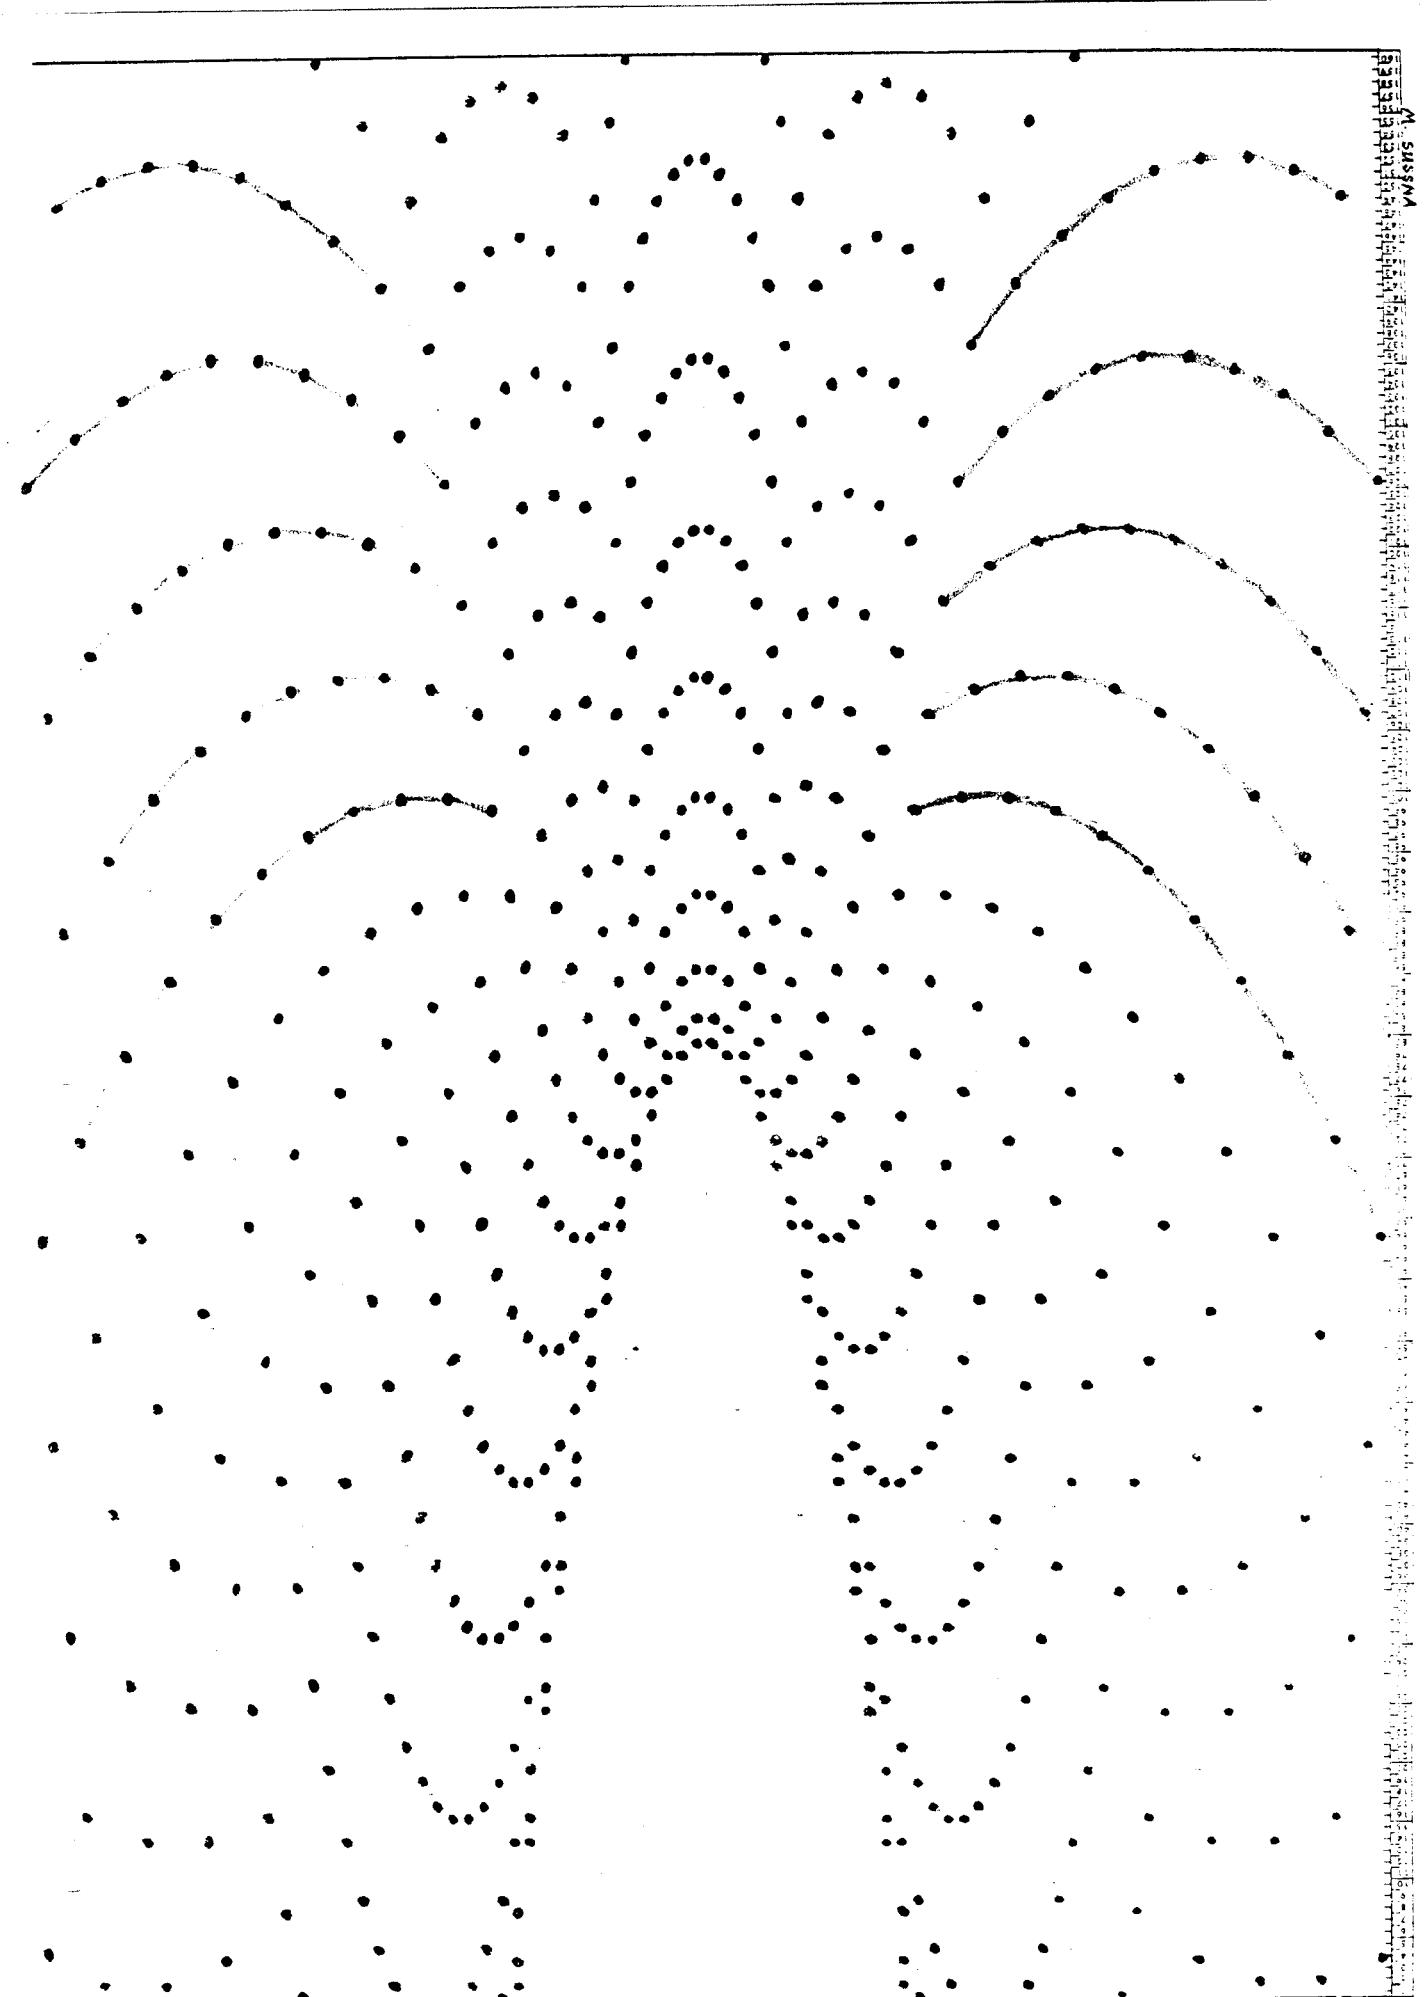

Figure 23.

WMSUS W  
WMSUS W

This trend toward wider families no doubt continues on both sides indefinitely.

Now, one may also note upward curving narrow curve families immediately adjacent to the void, on both its left and right. (See figure 27.)

And again, there are broader upward curving curve families to the left and right of the two void-adjacent families. (See figure 28.)

Here, too, the trend will continue outward on both sides.

In case anyone is interested, the formulas for the five above mentioned curve families' (left and right being considered equivalent) individual member curves when viewed as opening upward (for simplicity's sake) are:

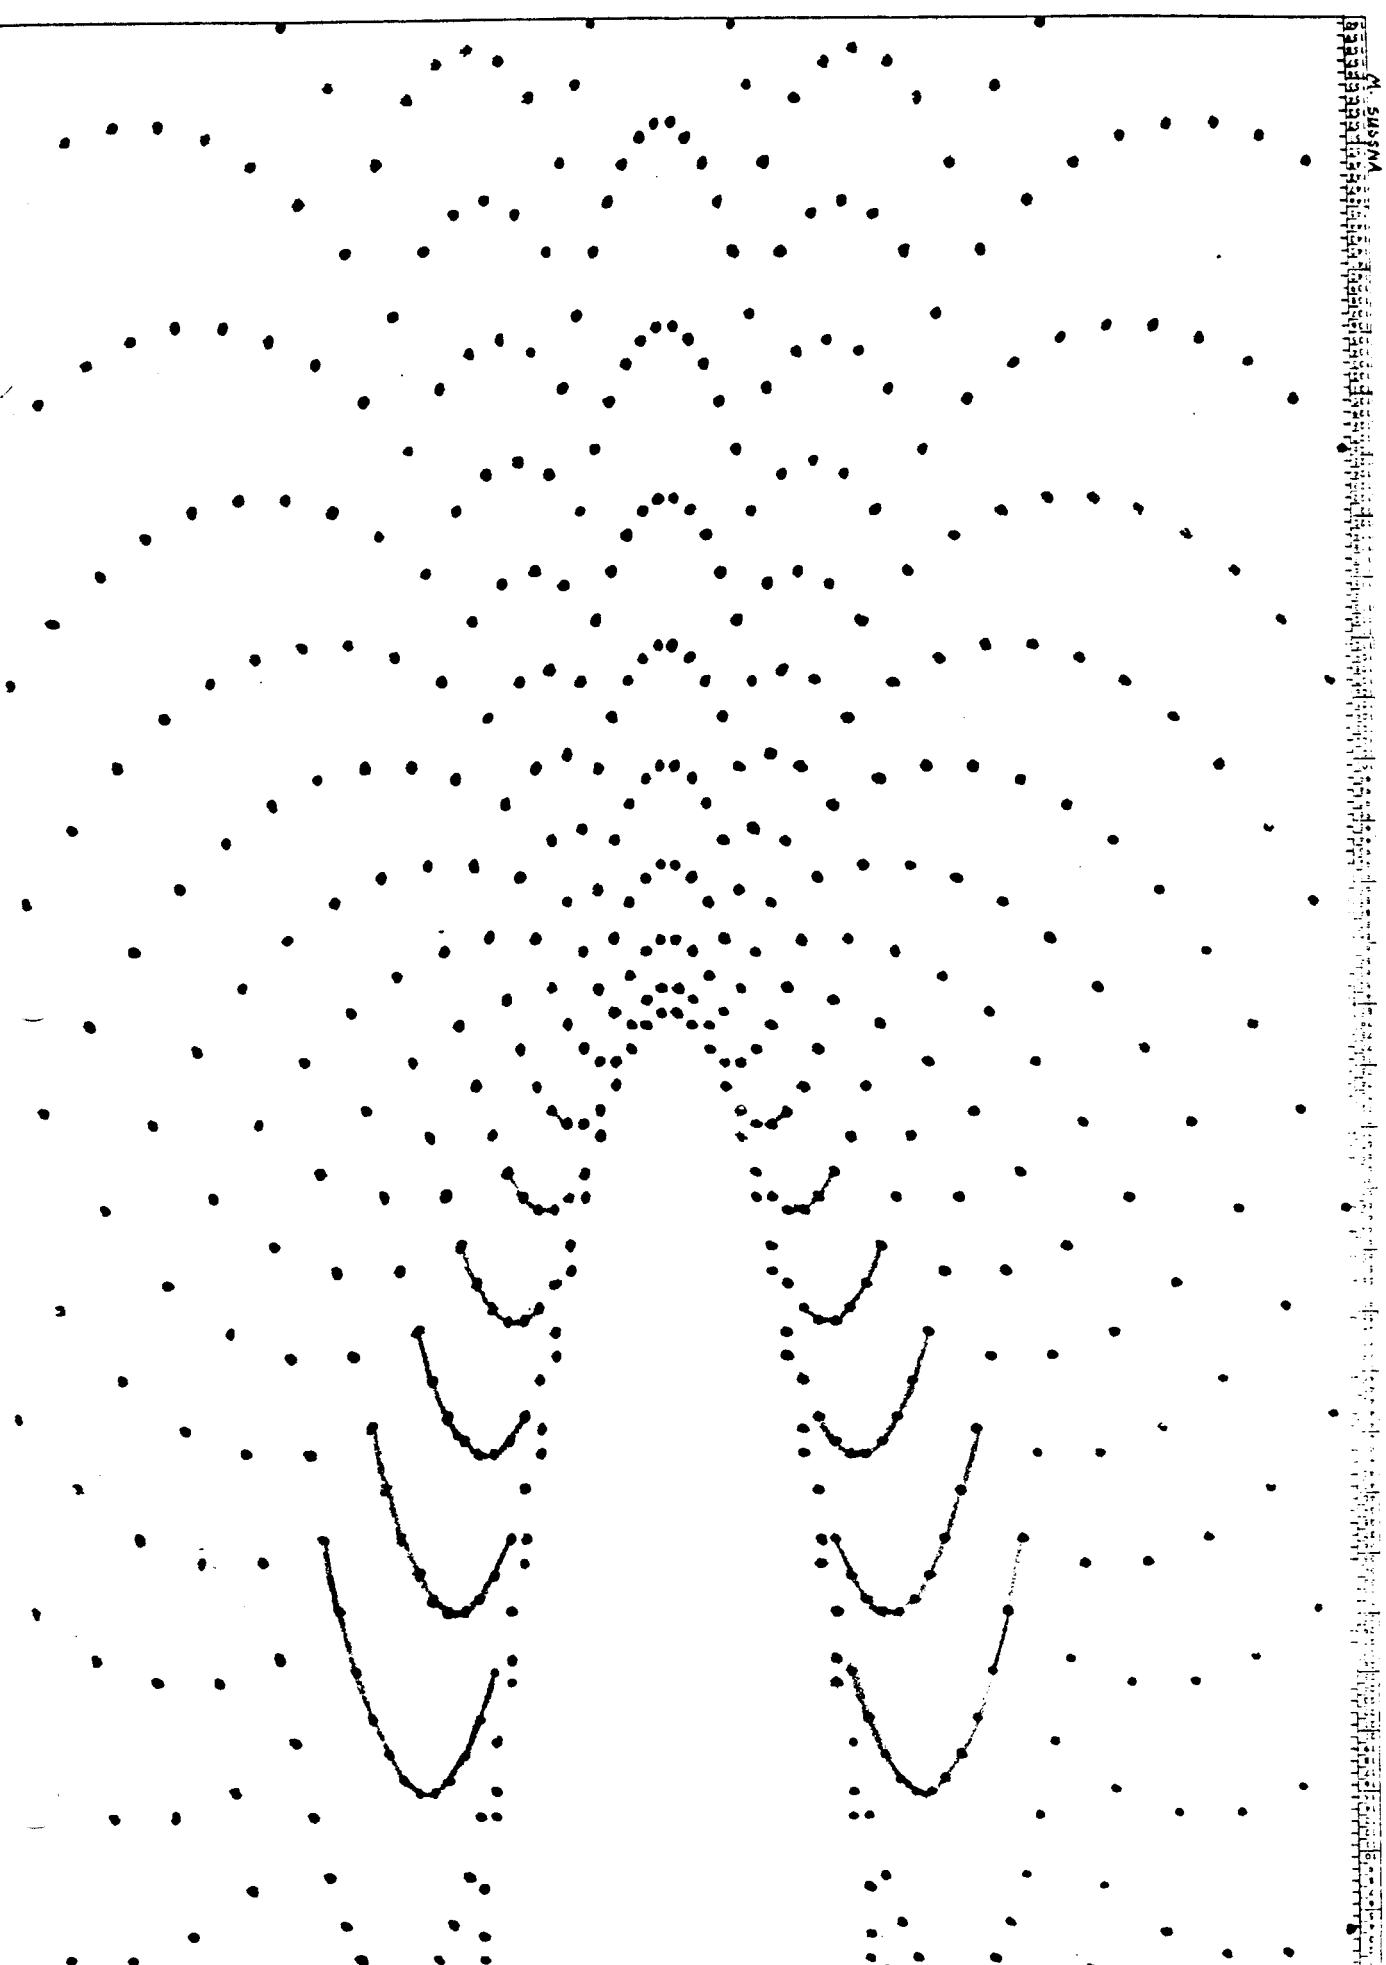

curve family	individual member
central	$\frac{1}{2x}^2 - \frac{1}{8}$
left and right center	$\frac{1}{4x}^2$
far left and right	$\frac{1}{18x}^2 - \frac{1}{8}$
void adjacent	$\frac{1}{2x}^2 - \frac{1}{8}$
outer void adjacent	$\frac{1}{16x}^2 - \frac{1}{4}$

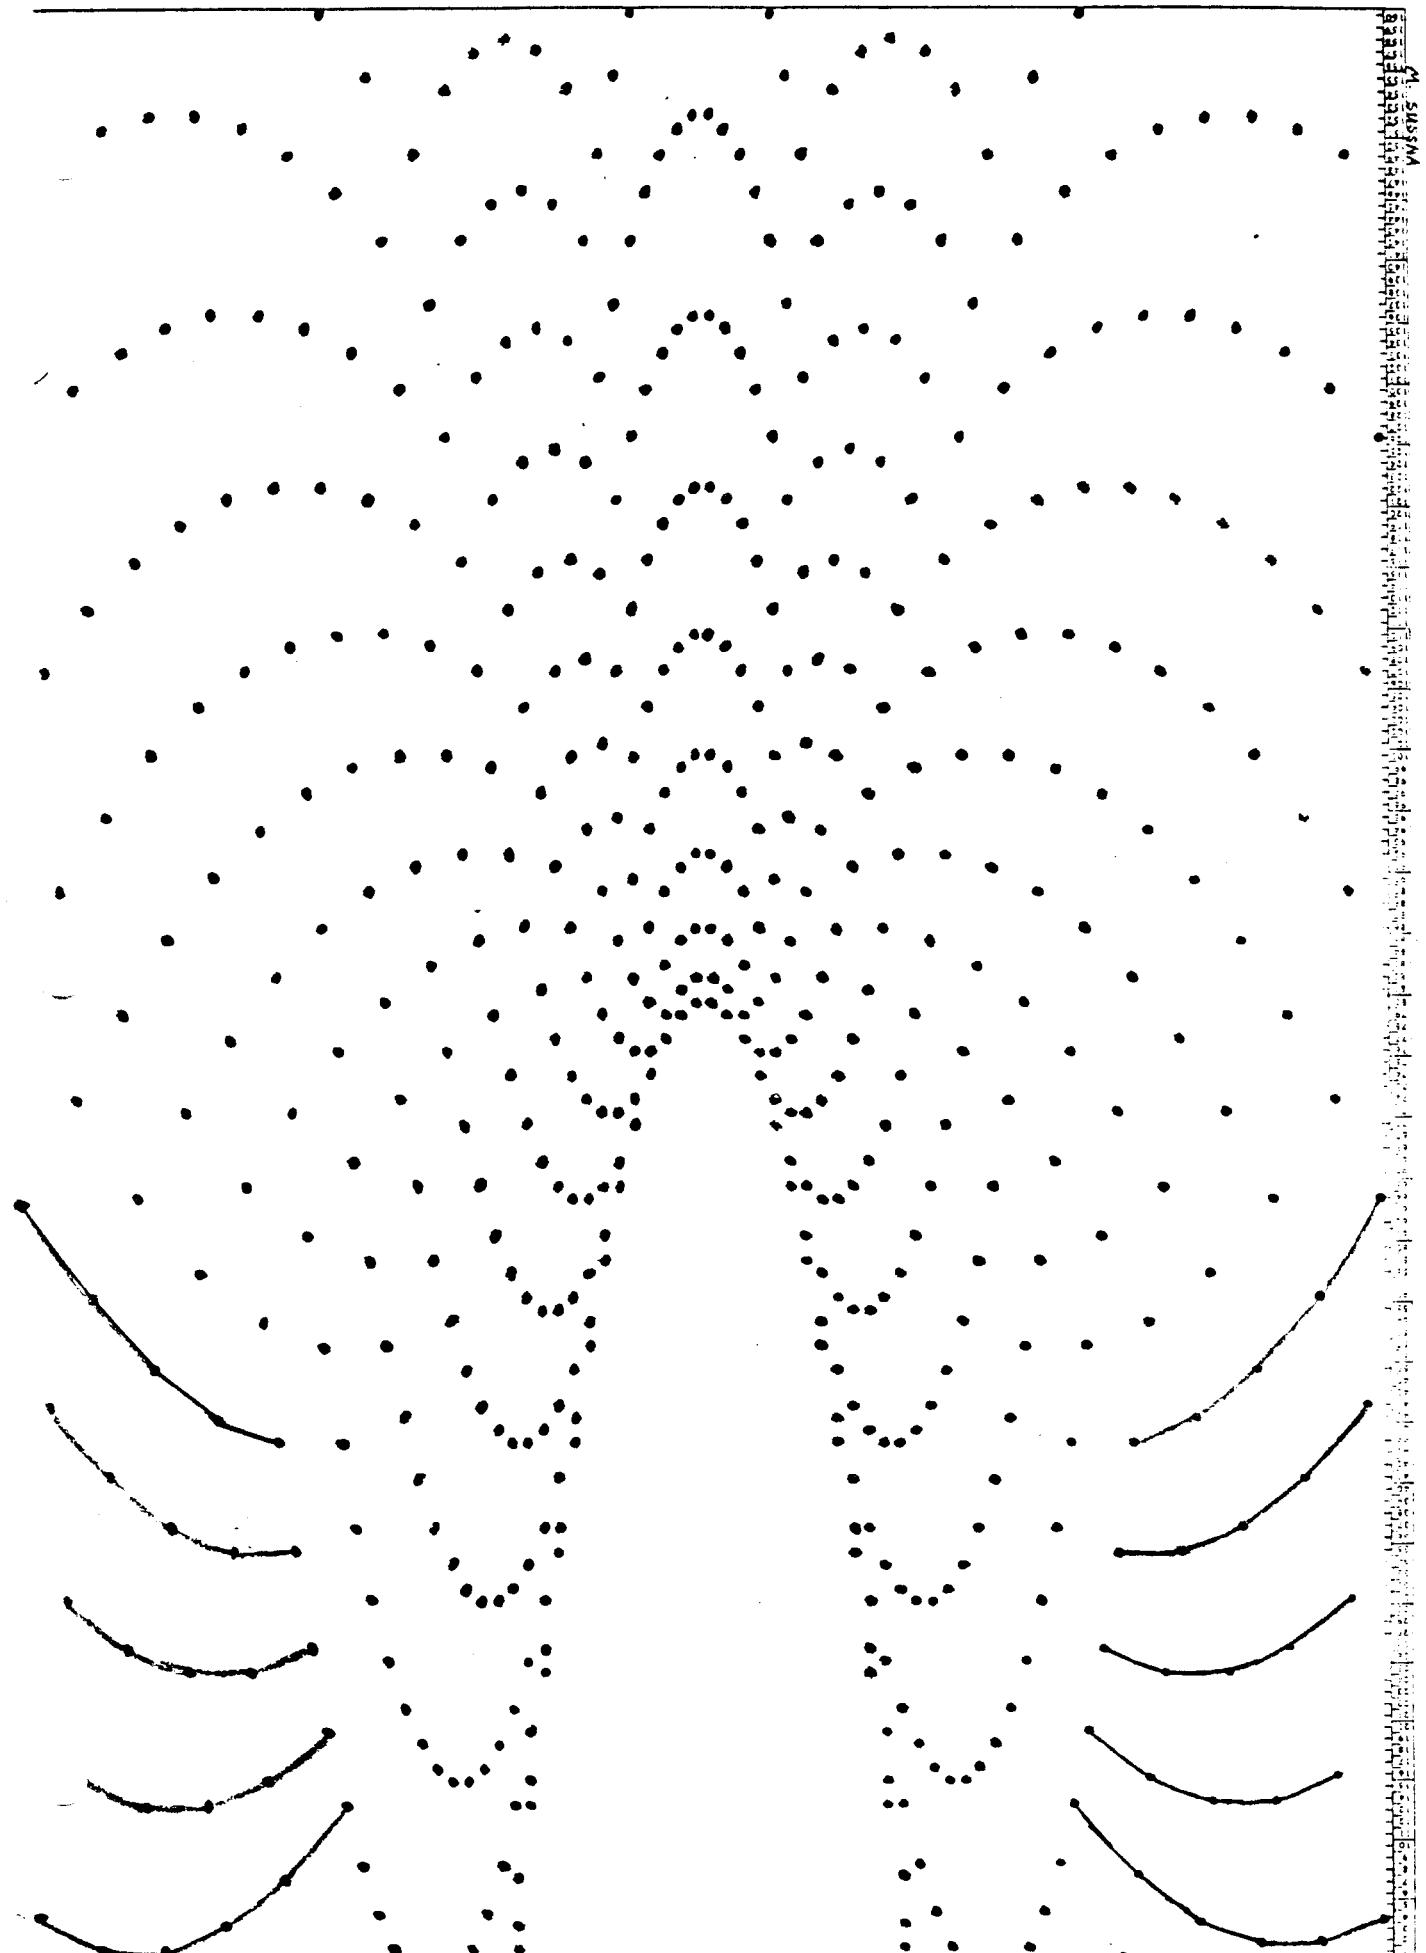

Figure 29.

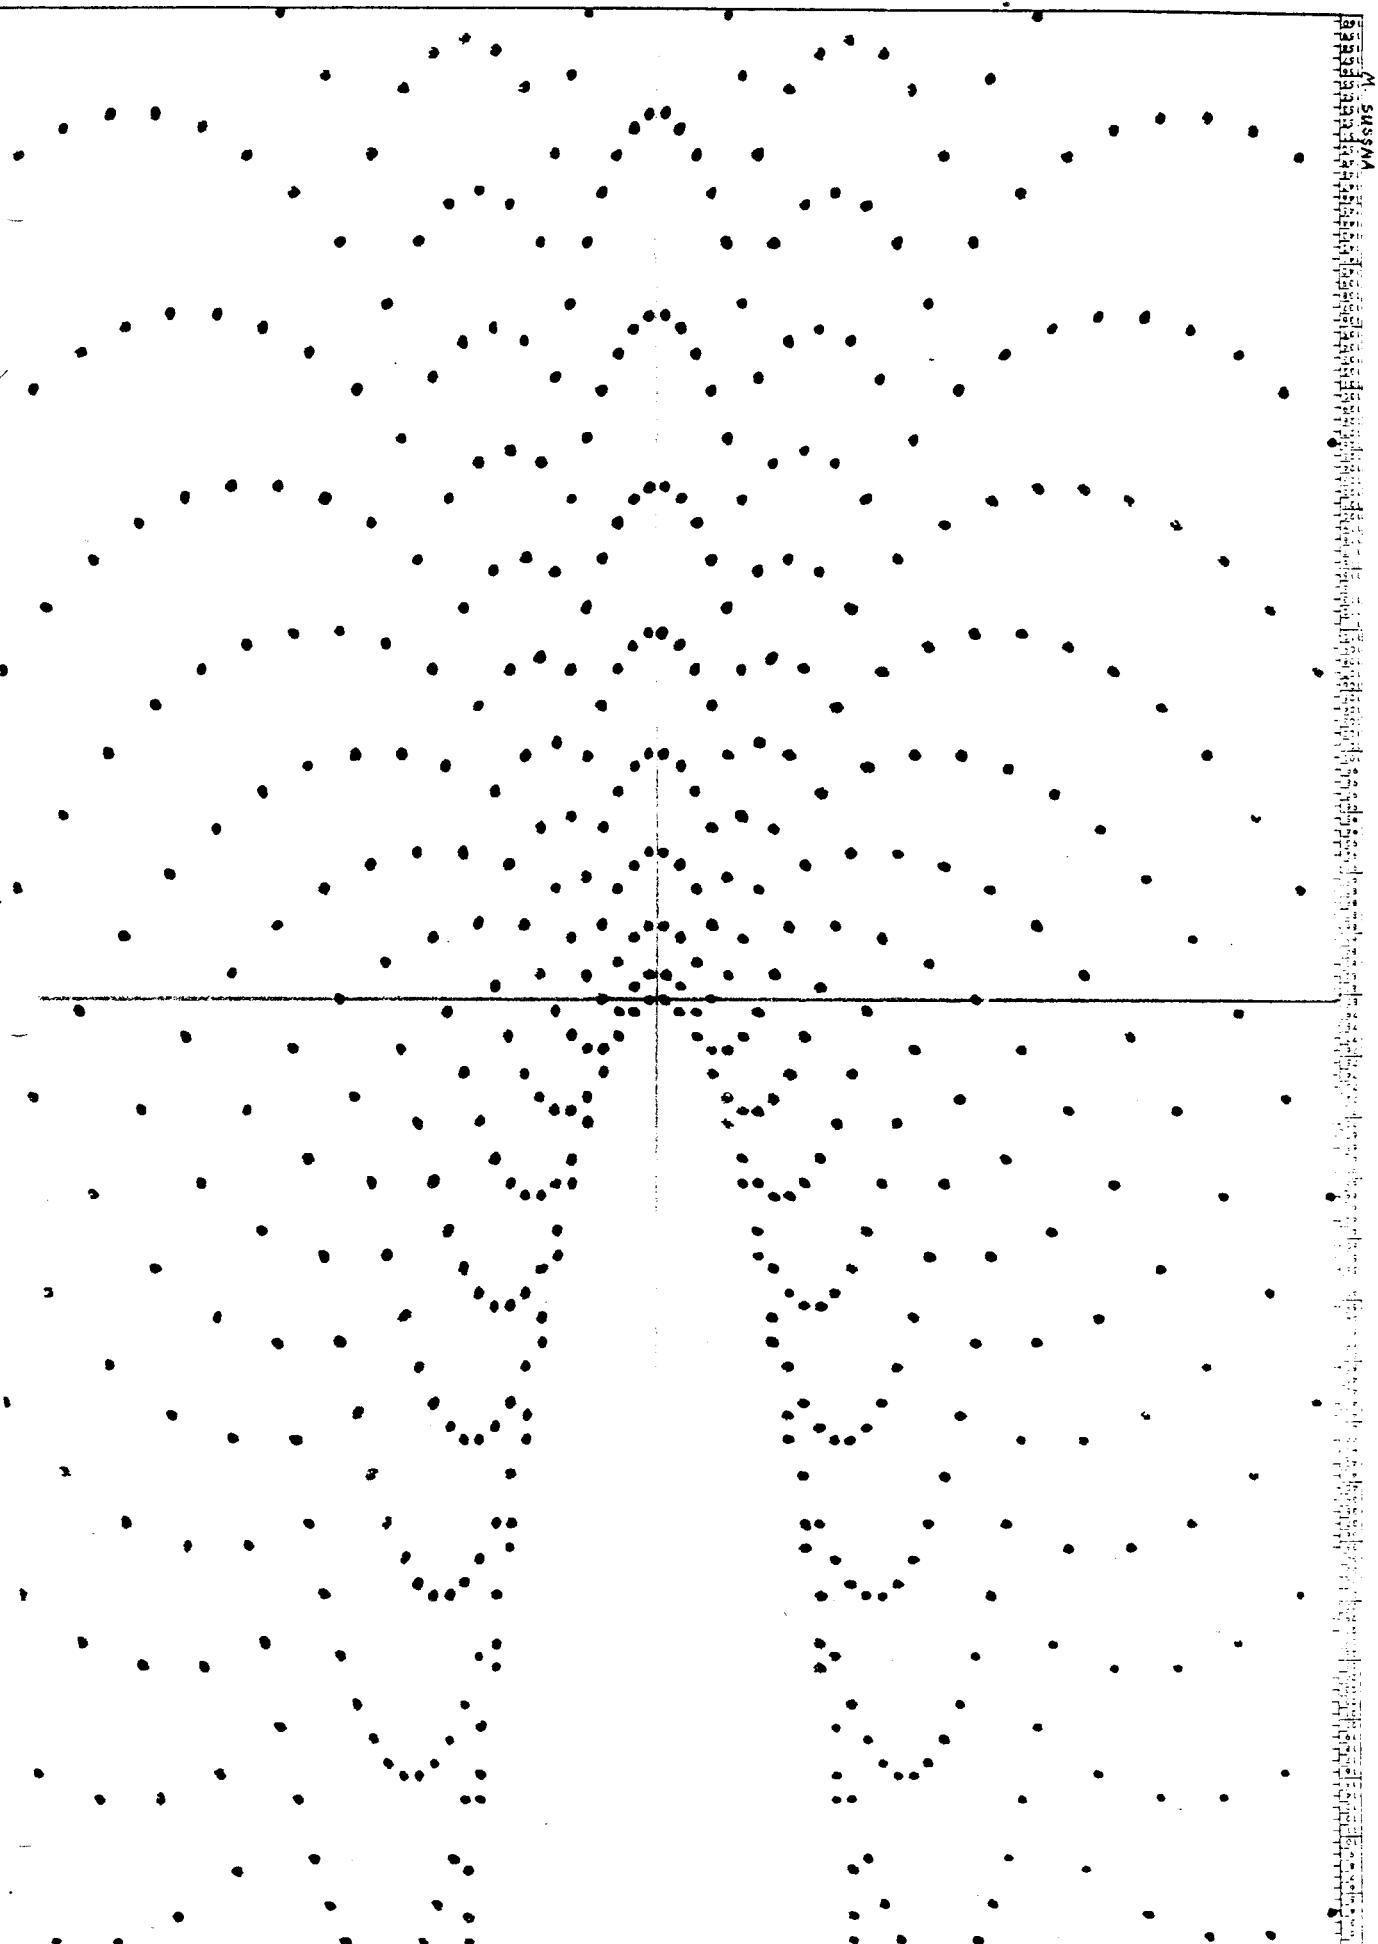

Another note on the curve families: "the design" seems to be divided into two halves not only down the middle when the void is at the bottom, but left to right at the vertex of the void, as well. (See figure 30.)

No downward curving curves have their vertex below the horizontal dividing line at the vertex of the void, while no upward curving curves have their vertex above that dividing line.

When "the design" is turned so that the void is either at the left or right, and viewed on edge, another surprise awaits us. There are completely empty swaths across the whole graph, sometimes more than one column wide. (See figure 31.)

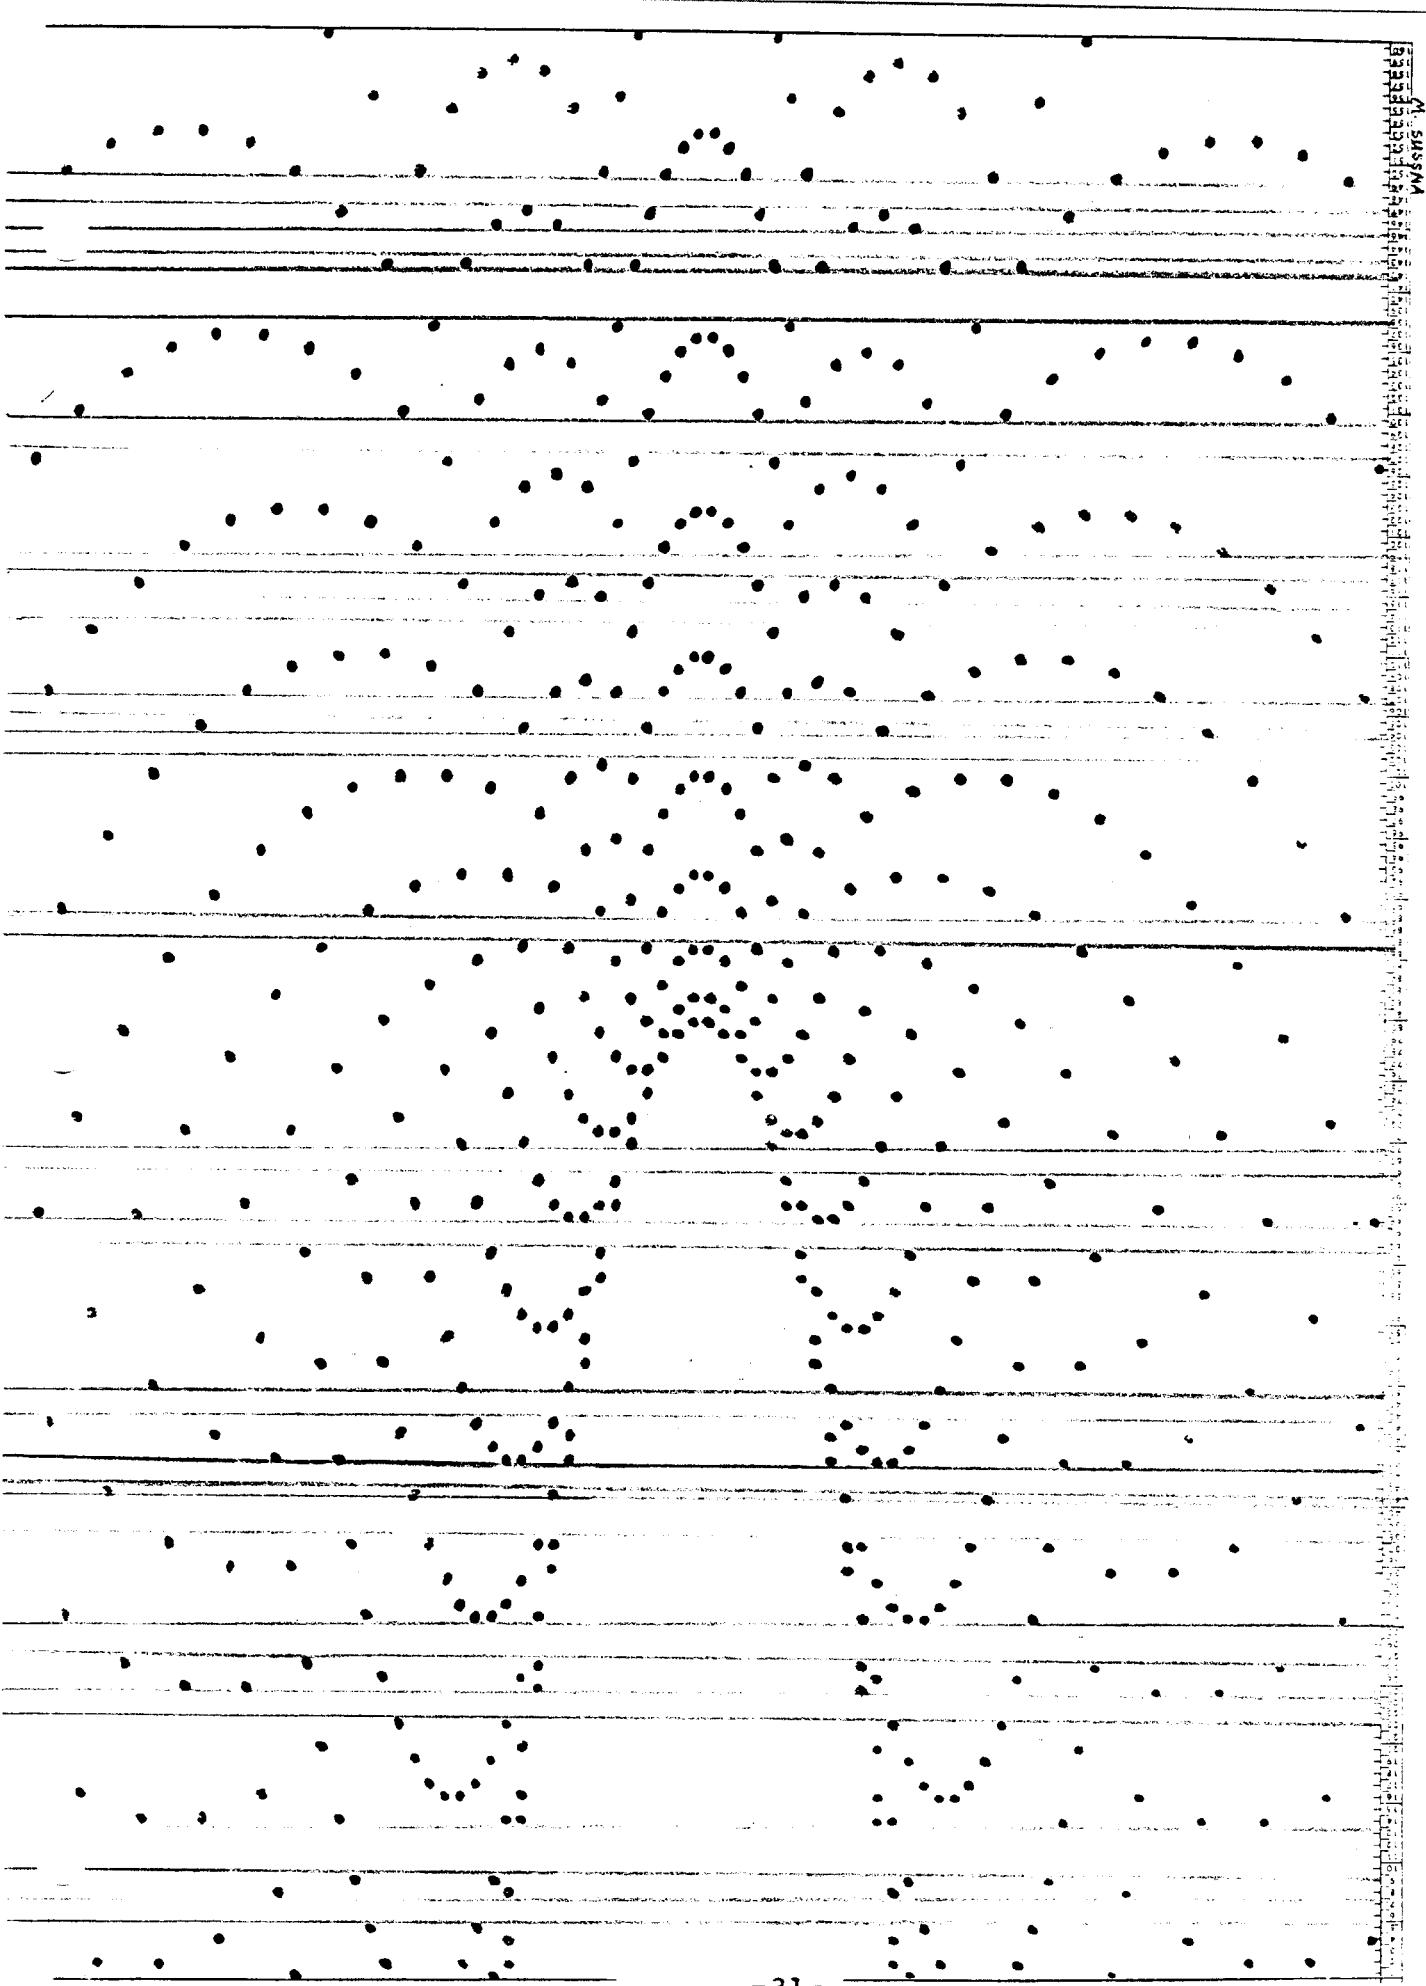

-30-

Figure 30.

Figure 31.

## 8. "THE DESIGN" ON EDGE

Look at "the design" from the void's open end, on edge.

The left and right void adjacent families now extend all the way to the other end of the paper and all the way to each side of the paper.

The far left and right void adjacent families have disappeared -- so have the left and right center downward curving families and the far left and right downward curving families.

The only families remaining are the left and right void adjacent families and the central downward curving family. (See figure 32.)

When "the design" is viewed in the same manner with the void at the top, one realizes that the entire "design" is one family! (See figure 33.)

## 9. GENERATING THE WHOLE "DESIGN" FROM ITS PARTS

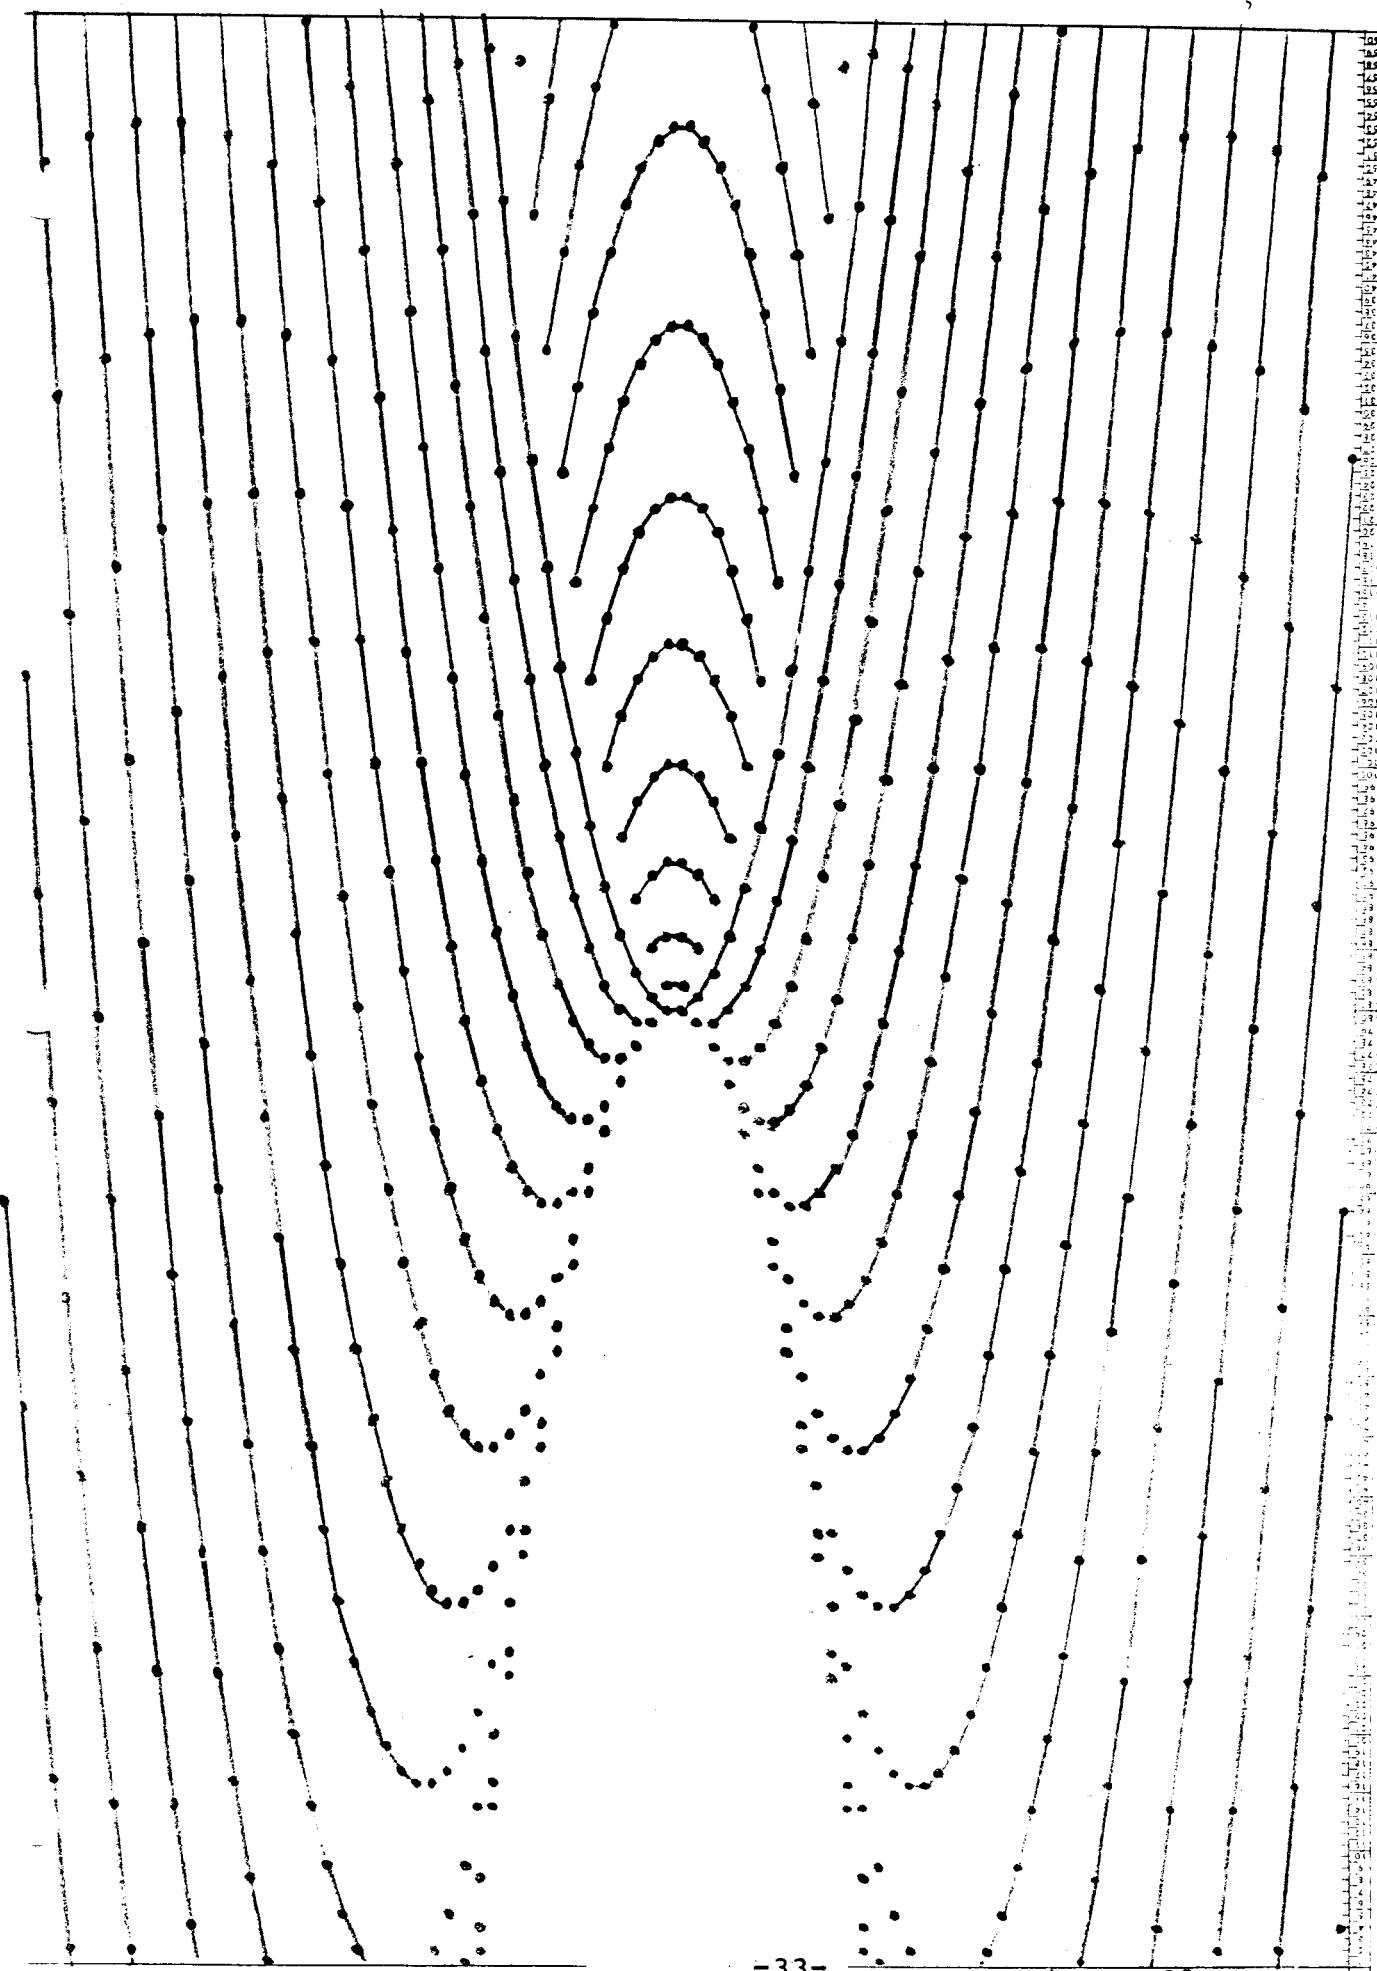

Thus, one of the most remarkable features of "the design" is that the entire "design" can be generated from one or another of its parts alone.

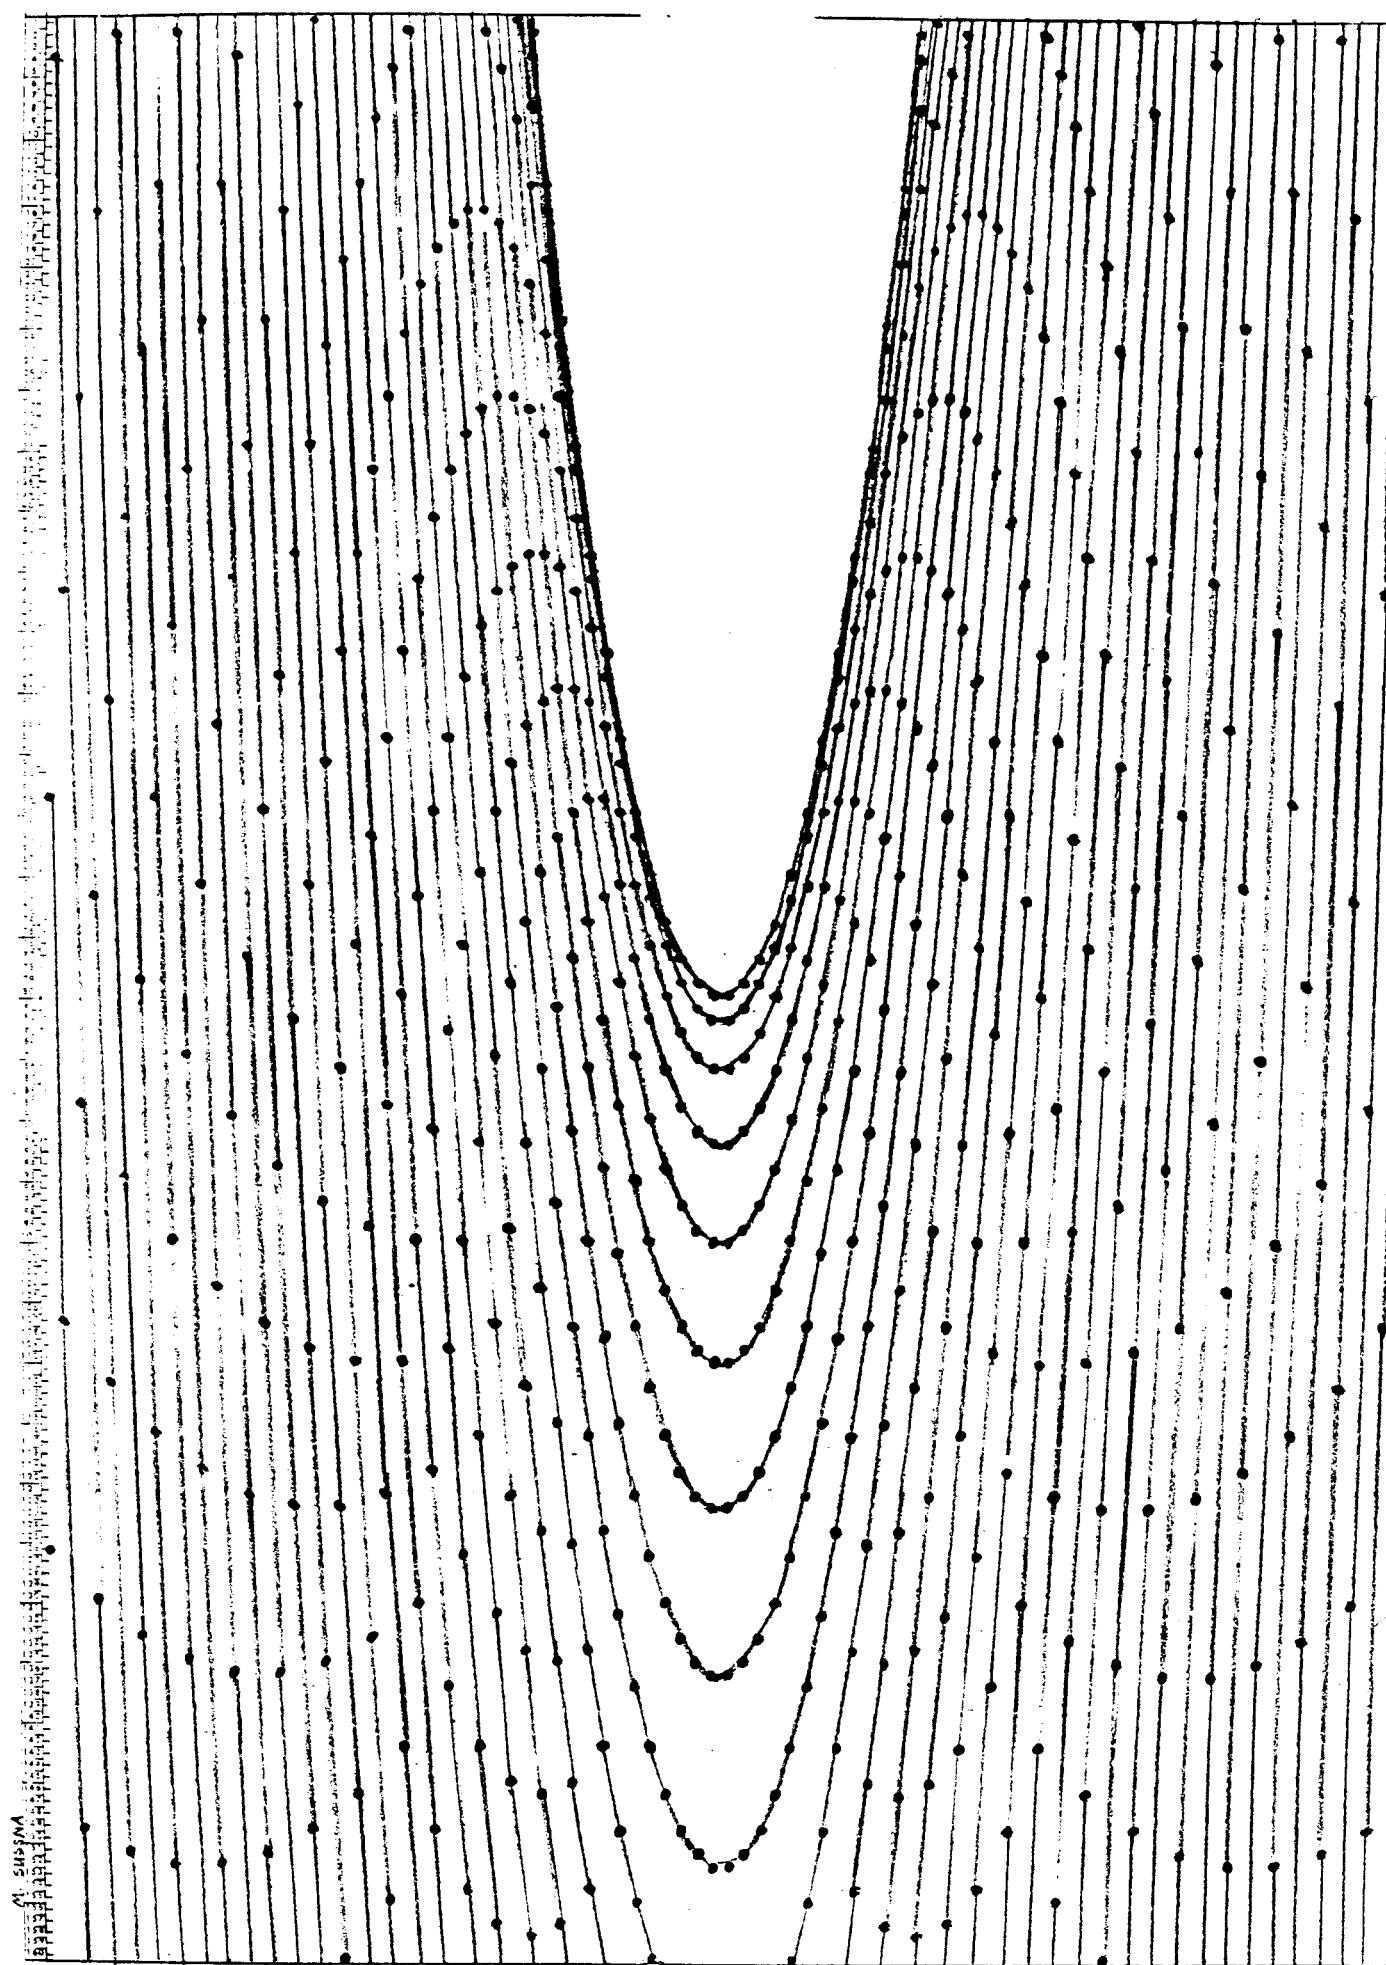

The central downward curving curve family can individually produce "the design", while each left and right pair of families, whether upward or downward curving, can do the same. Words don't suffice to tell you -- let me show you:

Take the central downward curving curve family. Start first with a single member of the family -- say the one with its vertex at the vertex of the void. (See figure 34.)

Now extend the family by adding members above the first member. Each succeeding member is directly above and the exact same shape as each of its predecessors. If the first curve, the one with its vertex at the vertex of the void, has its vertex at  $y=0$ , then the next curve above it has its vertex at  $y=2$ , the curve above that has its vertex at  $y=6$ , and so on. In general, the central downward curving curve  $z$  has its vertex at  $y = z^2 + z$ , where  $z=0$  for the curve whose vertex coincides with that of the void. (See figure 35.)

This adding on of curves has an intriguing effect as it proceeds: the more curves that are added on, the more "design" that is finished. The "completing" moves out in every direction from the center of "the design", the vertex of the void. (This is the old "convergence point" whose lure drew me out past the confines of the graph containing the triangular array.) As the number of curves grows in-

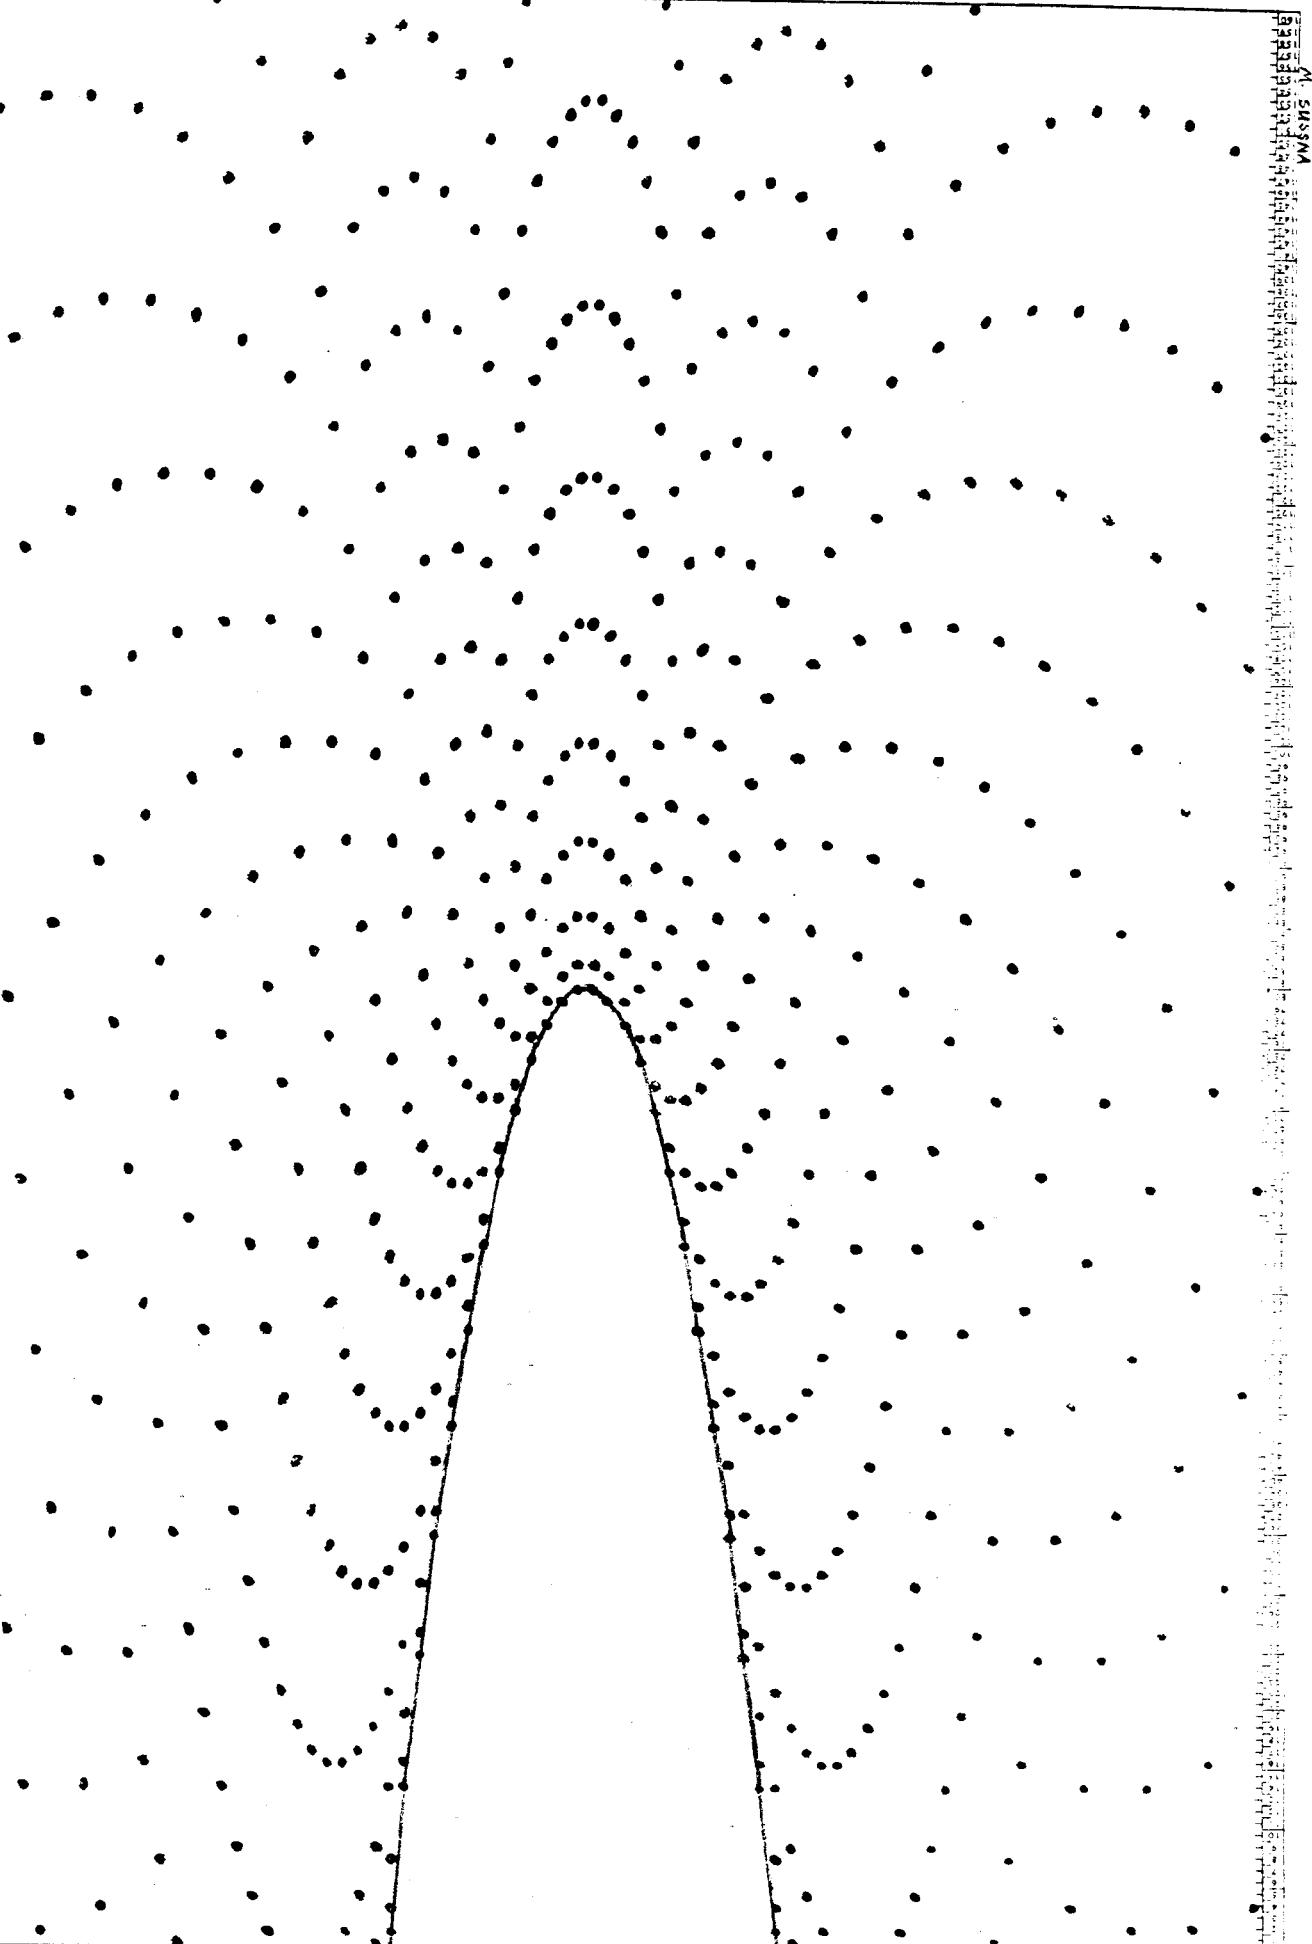

Figure 34.

Figure 35. A contour map showing the distribution of a variable across a field. The map consists of numerous small dots representing data points, which are connected by a series of concentric, roughly elliptical contour lines. The contours are more densely packed in the center of the field, indicating higher values of the variable, and spread out towards the edges. The overall shape of the contours is roughly rectangular.

definitely great, the area of "design" also grows, almost as greatly. For example, only about 32 curves of the central downward curving curve family are needed in order to generate the entire "design" as presented here. (See figure 36.) In "the design" presented here, the edge of the paper at the wider end of the void is an arbitrary truncation of all the central downward curving curves that intersect it. In fact, all central downward curving curves intersect it. Of course the same is true of all four sides of any rectangular representation of a central portion of "THE DESIGN": they all truncate the "true" "DESIGN" - that is, the true "DESIGN" goes on endlessly in every direction. Thus any of our attempts to render it produce necessarily limited pictures of it.

Taken together, the left central downward curving curve family and the right central will produce the entire "design" in much the same way, and so on for any left and right downward or upward curving curve family pair. (See figures 37-40.)

One thing this generation of the whole from any of its parts process reminds me of is the biological regeneration of an organism from one limb, as in the starfish, or even from a single cell, as in cloning.

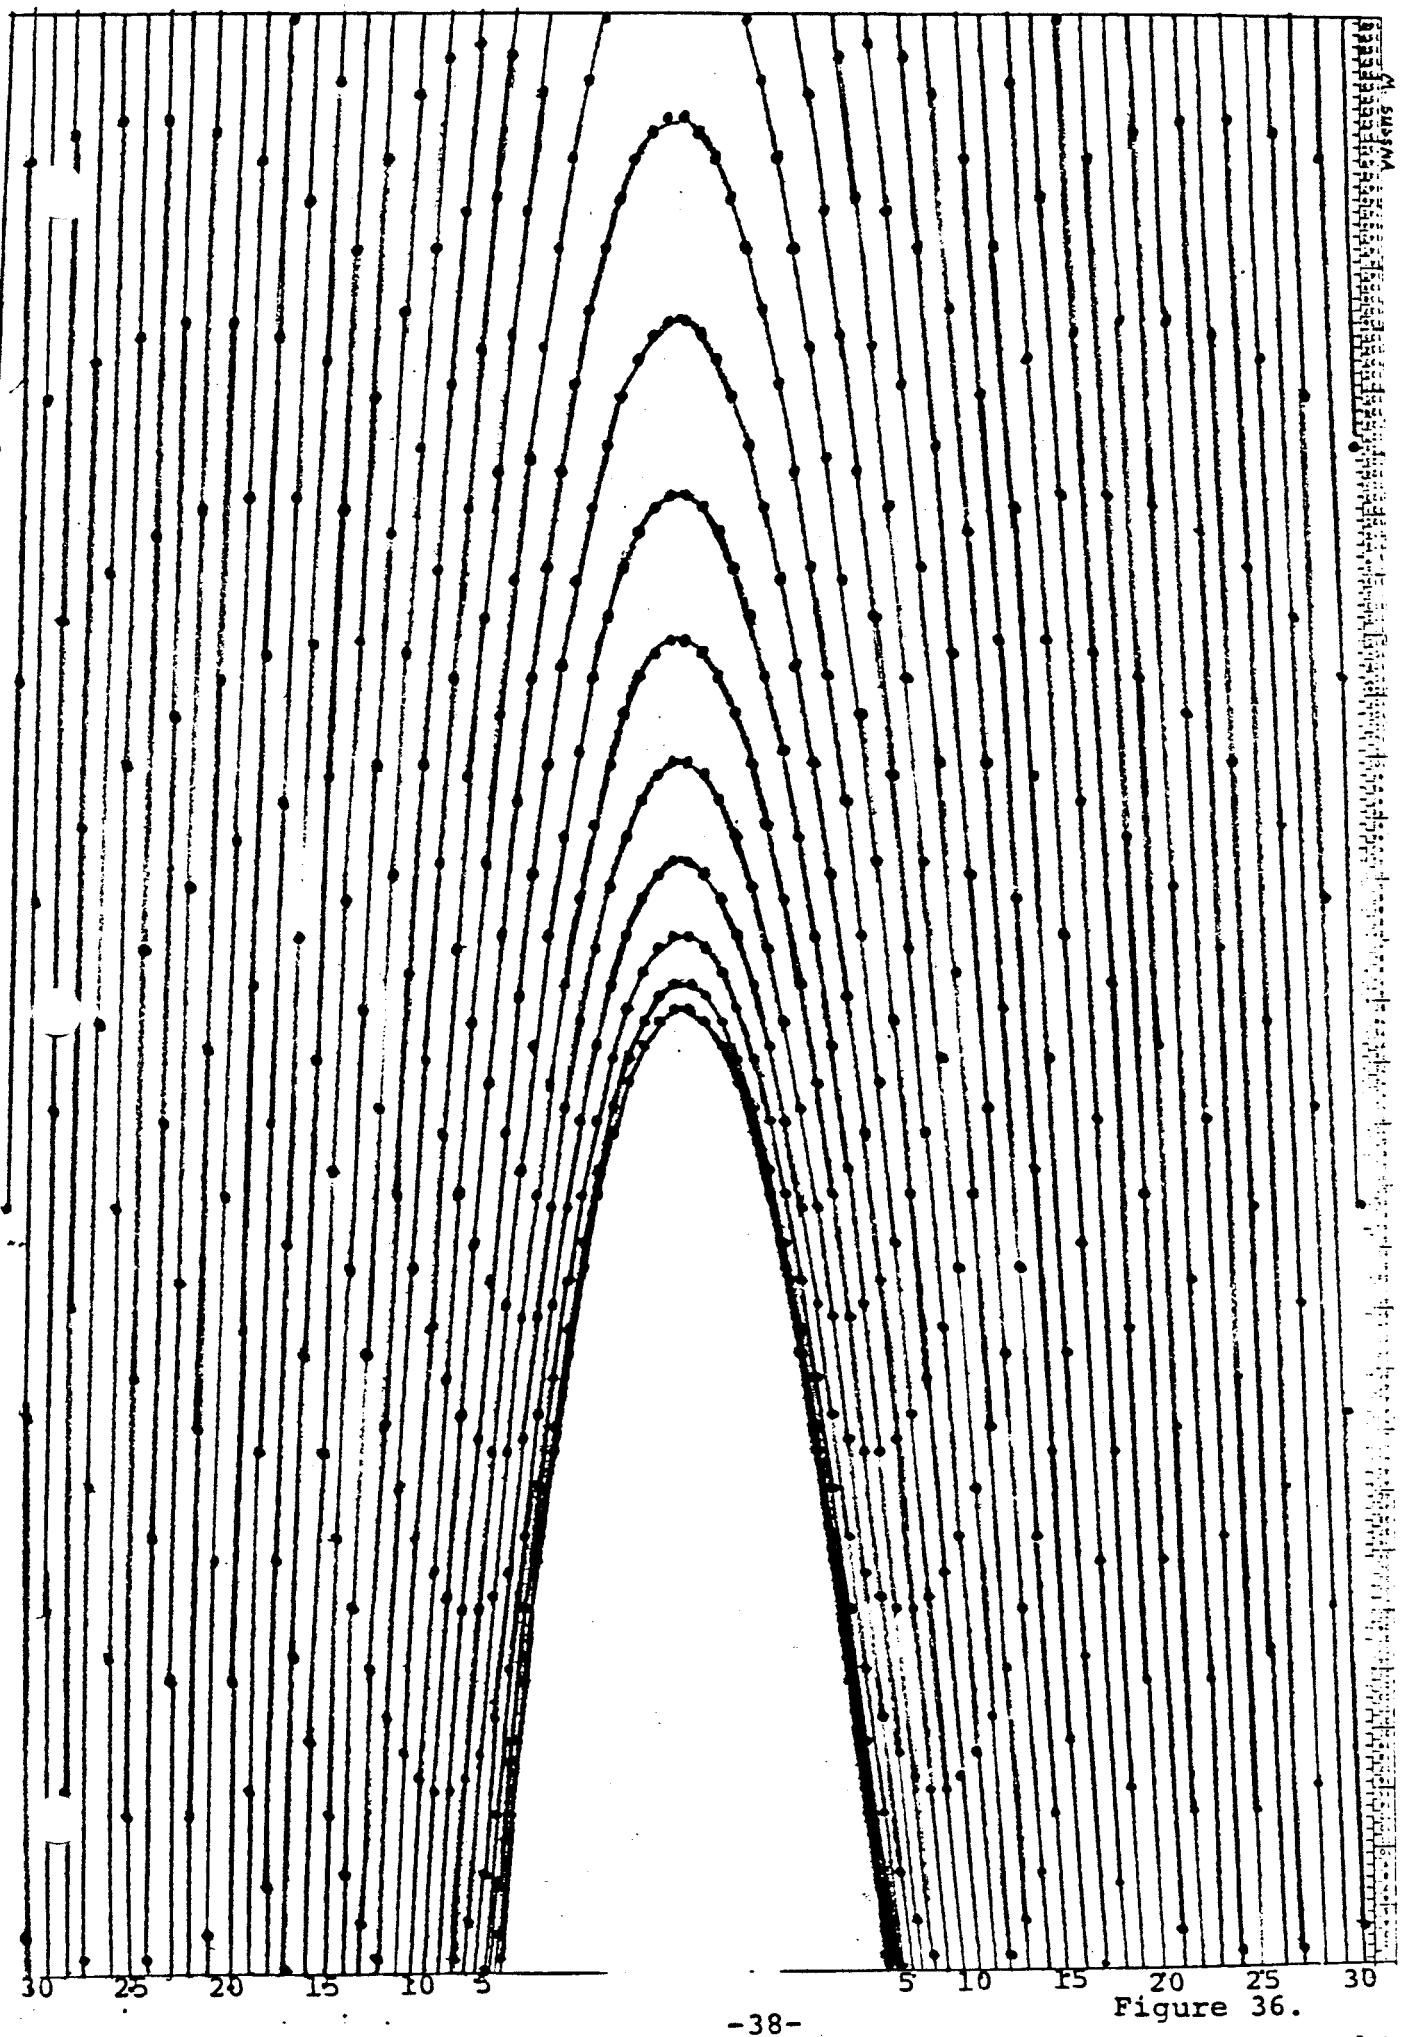

"The design" has elements of multiplicity in its many curve families. It has elements of duality in its bilateral symmetry and the pairs of curve families. It also has elements of unity in that a single curve family can generate the whole "design" and that each dot is a member of all curve families. The multiplicity of its parts is complemented by the unity of the whole. In other words, although from one point of view (looking at it from above) there appear to be many subsections to the "design" (the curve families), from another perspective (looking at it on edge) there is only one curve family. Which viewpoint is correct? Both are!

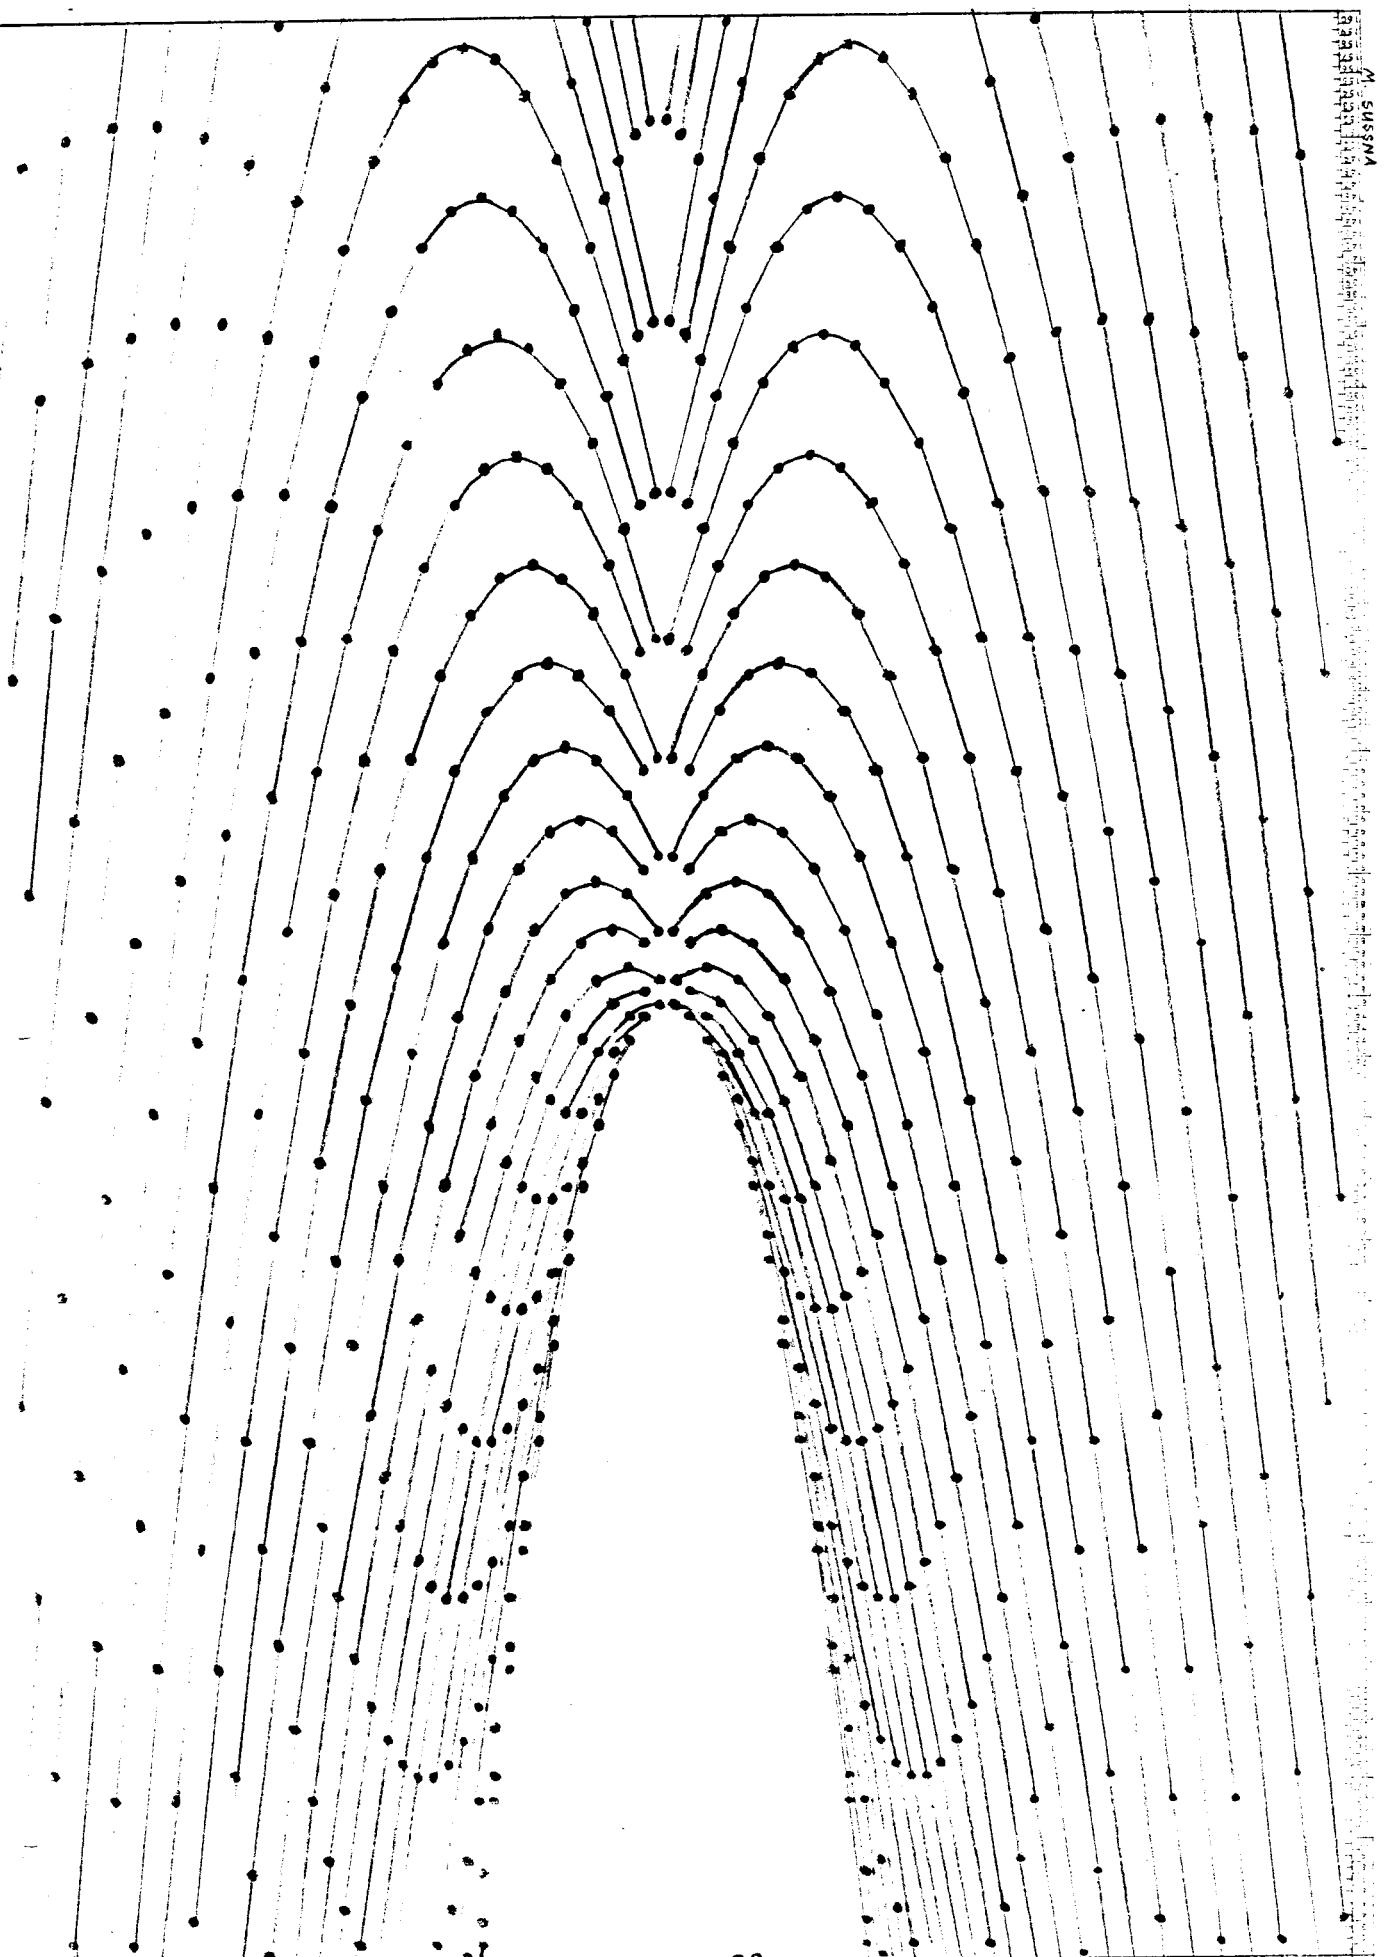

Thus, philosophically speaking, the one and many each is illusory from the perspective of the other, but the truth is that both are valid.

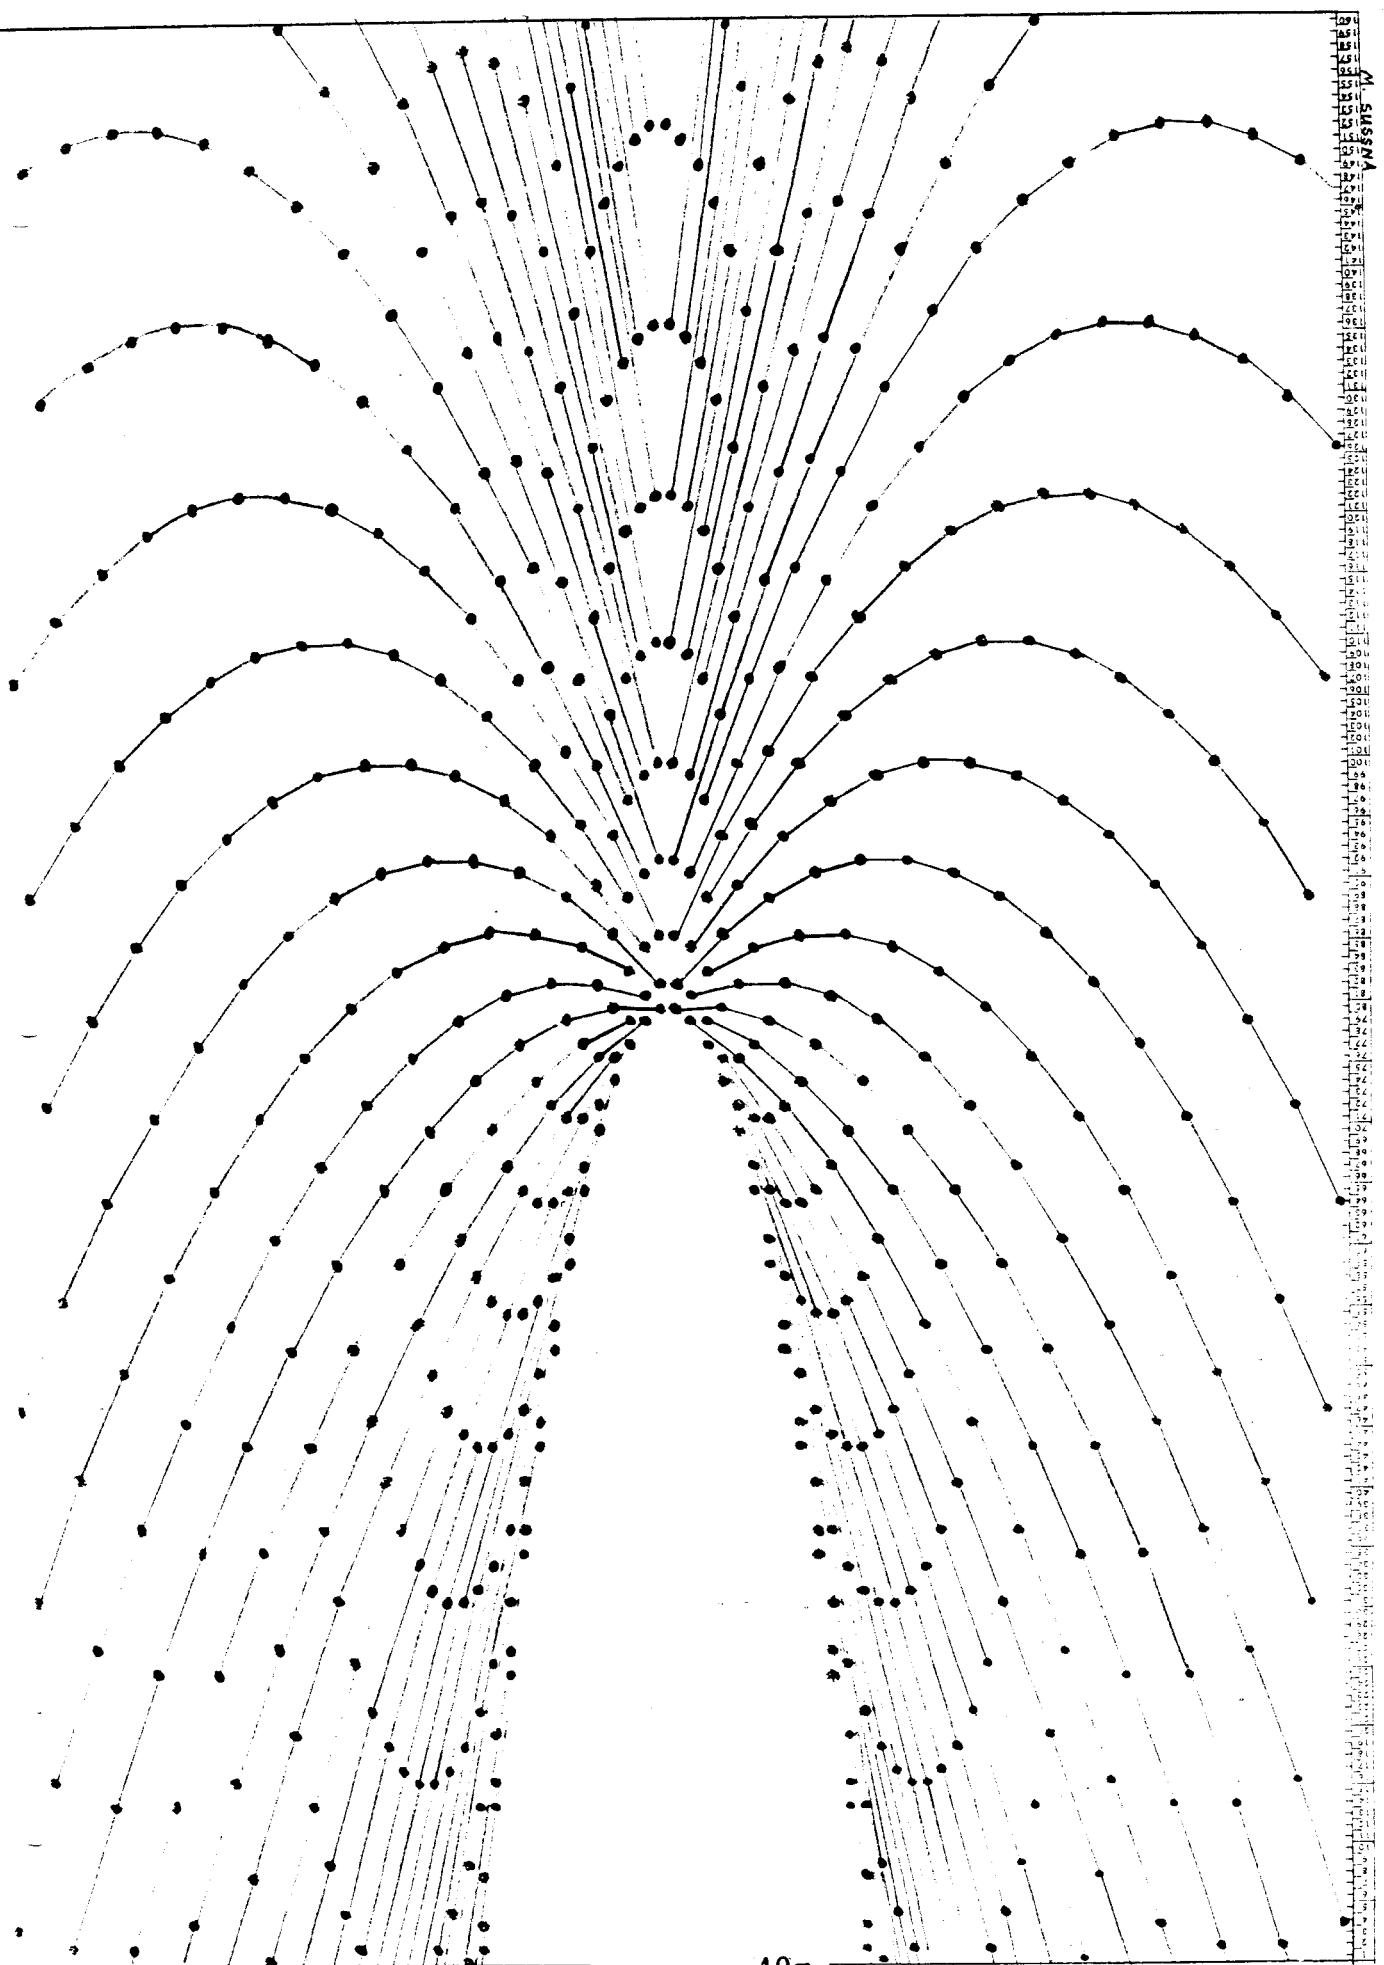

#### 10. DOTTED LINES TO THE NORTHEAST

Some of my more recent findings include the following.

The values of the  $2x^2$  formulas, as you will recall, appear as straight lines of primes on the triangular array. Early on I had asked myself what happened with the values when  $x$  is between zero and the number generating the first value in a given straight line. At that time I had simply plotted those lower values on the triangular array. They formed curves as seen in figures 41-45.

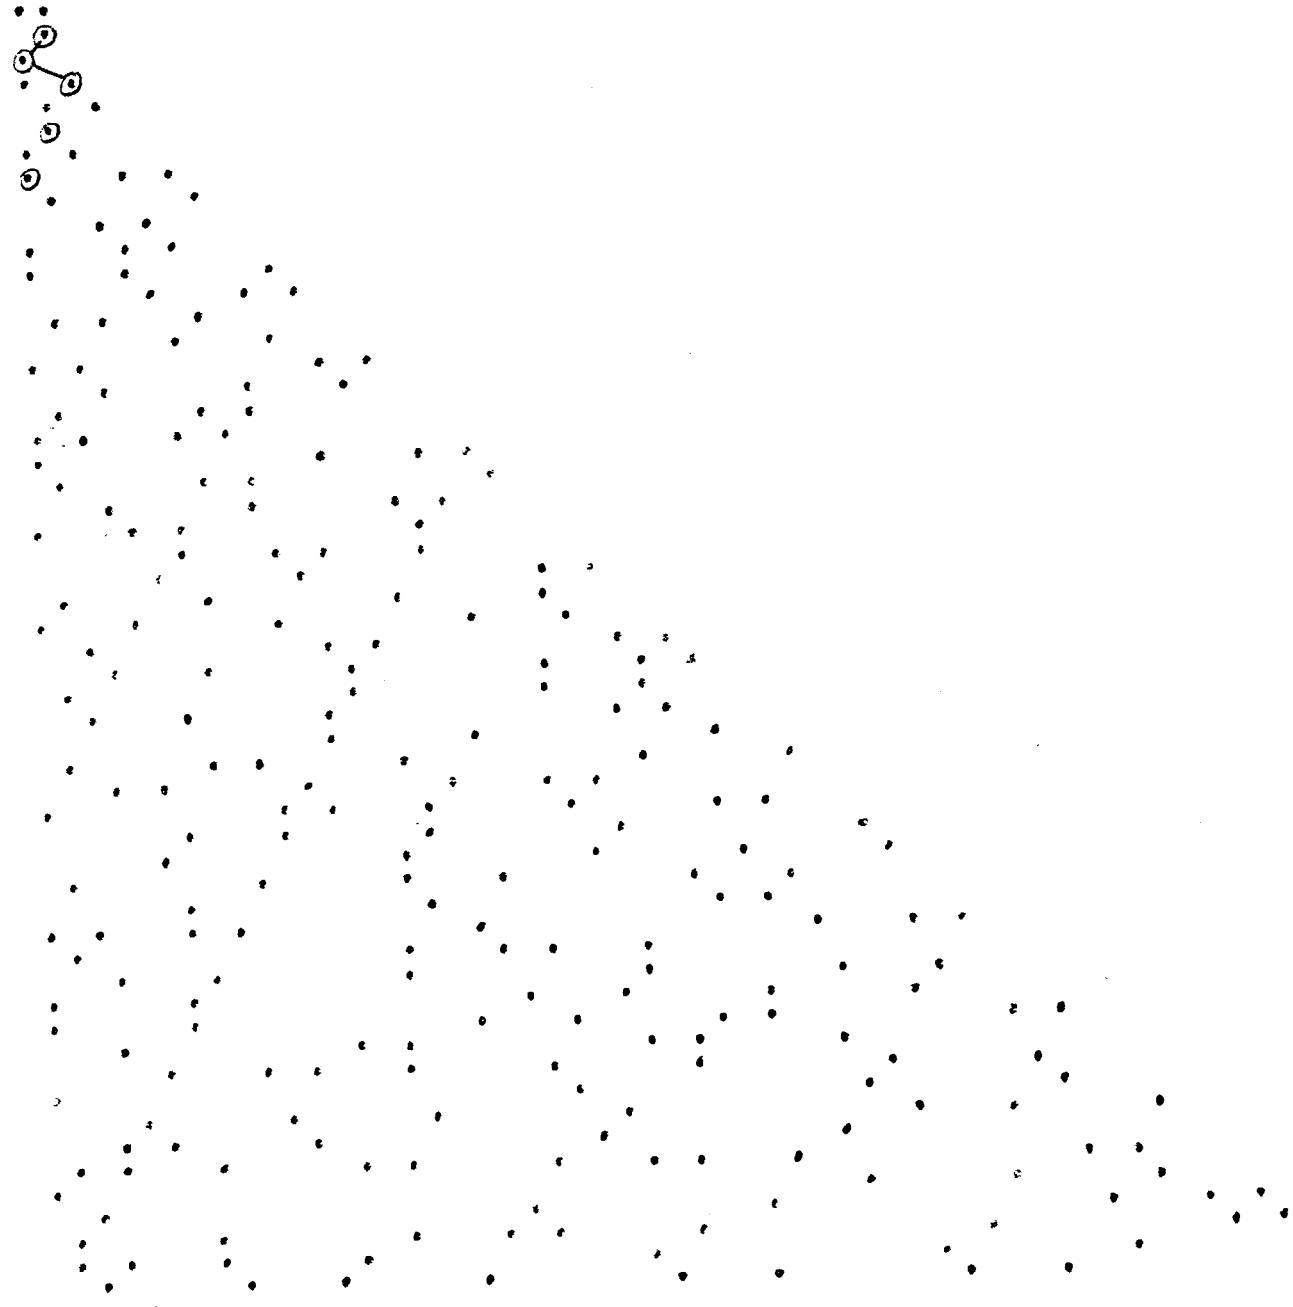

Figure 41.

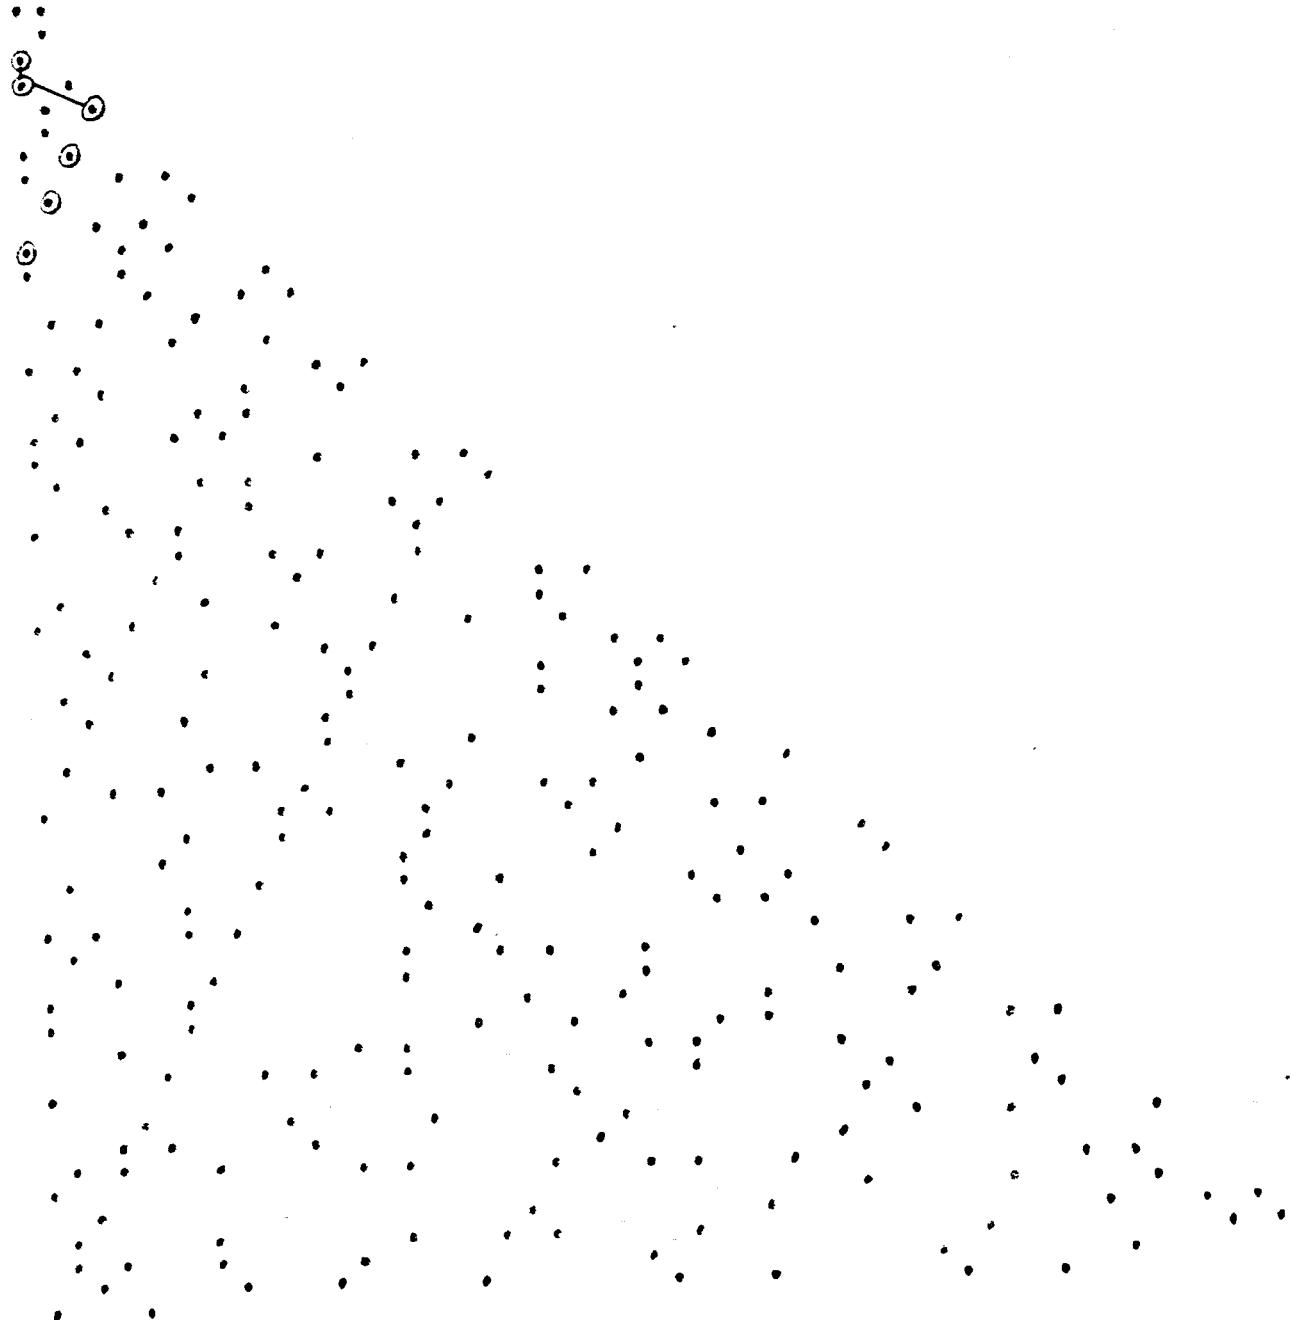

Figure 42.

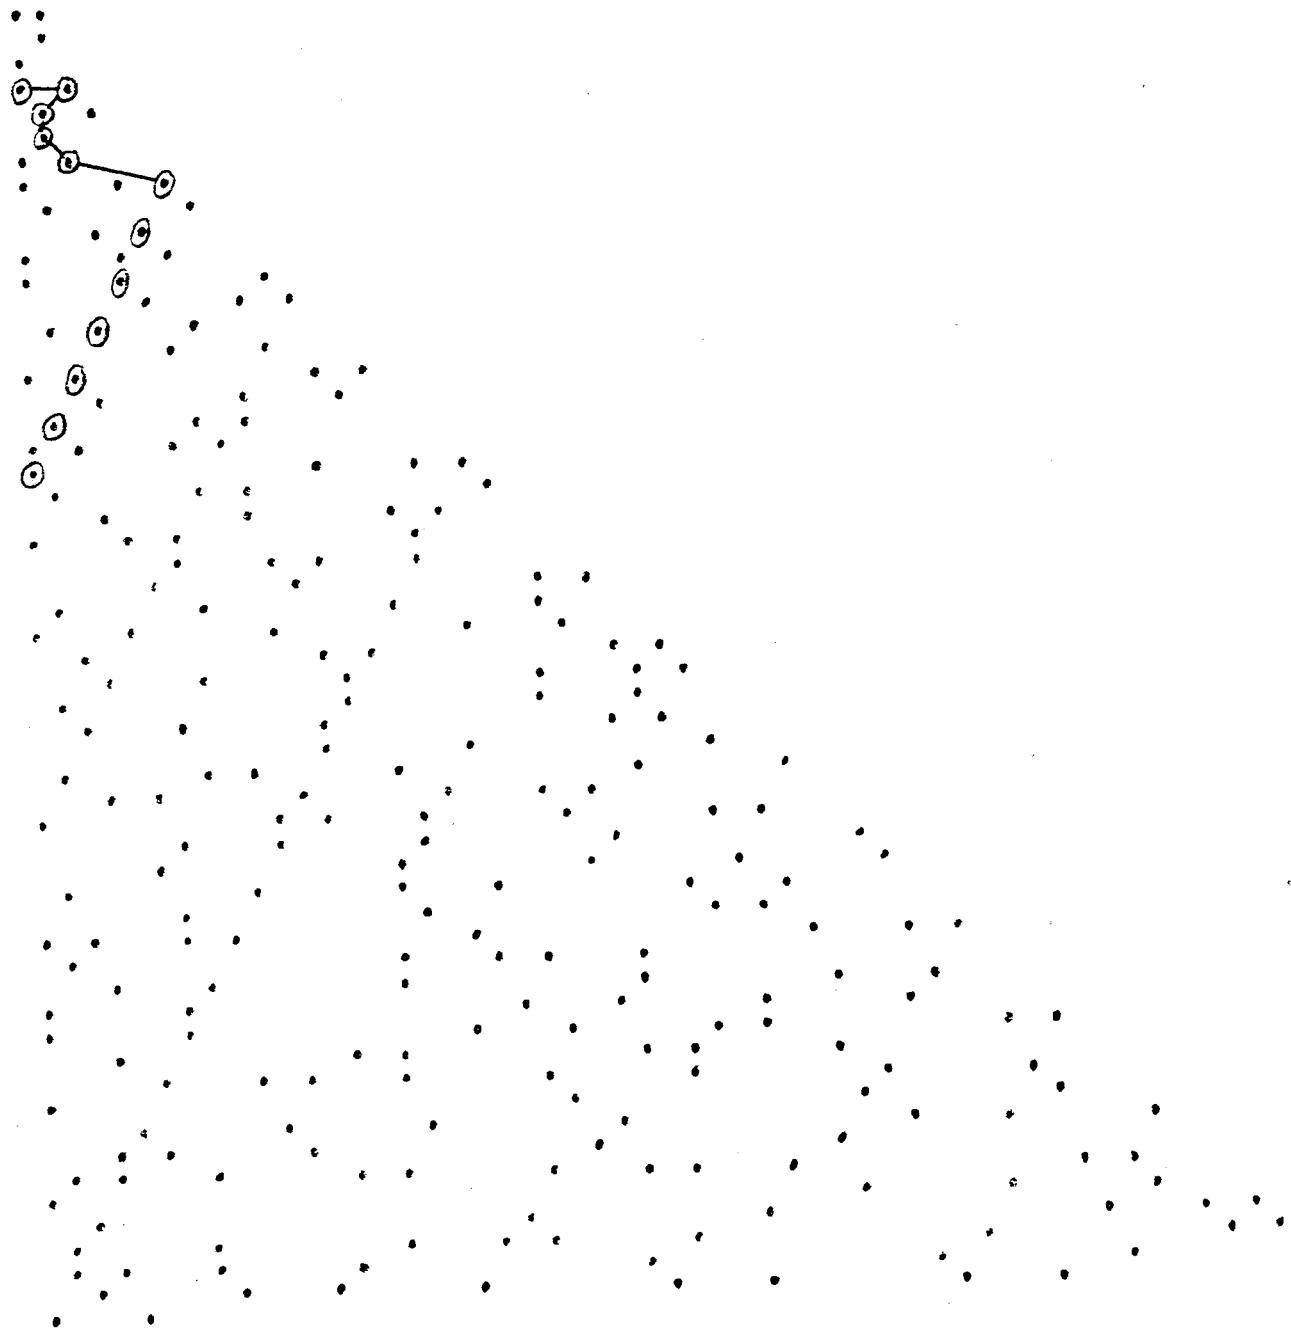

Figure 43.

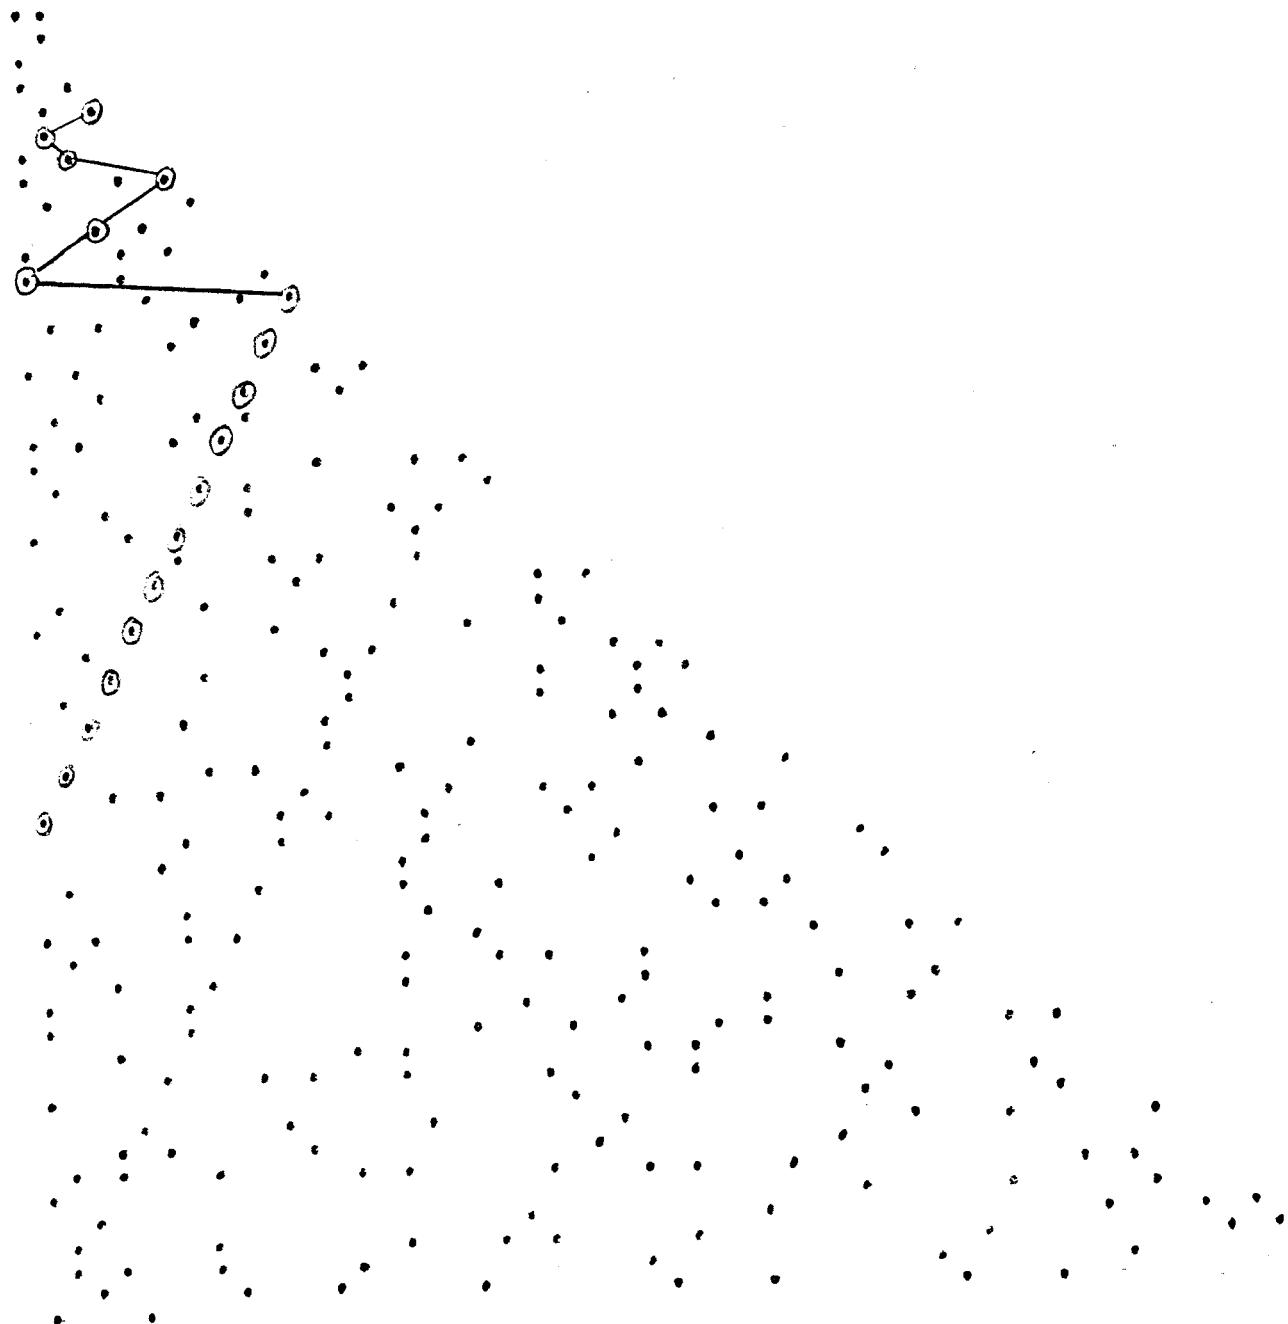

Figure 44.

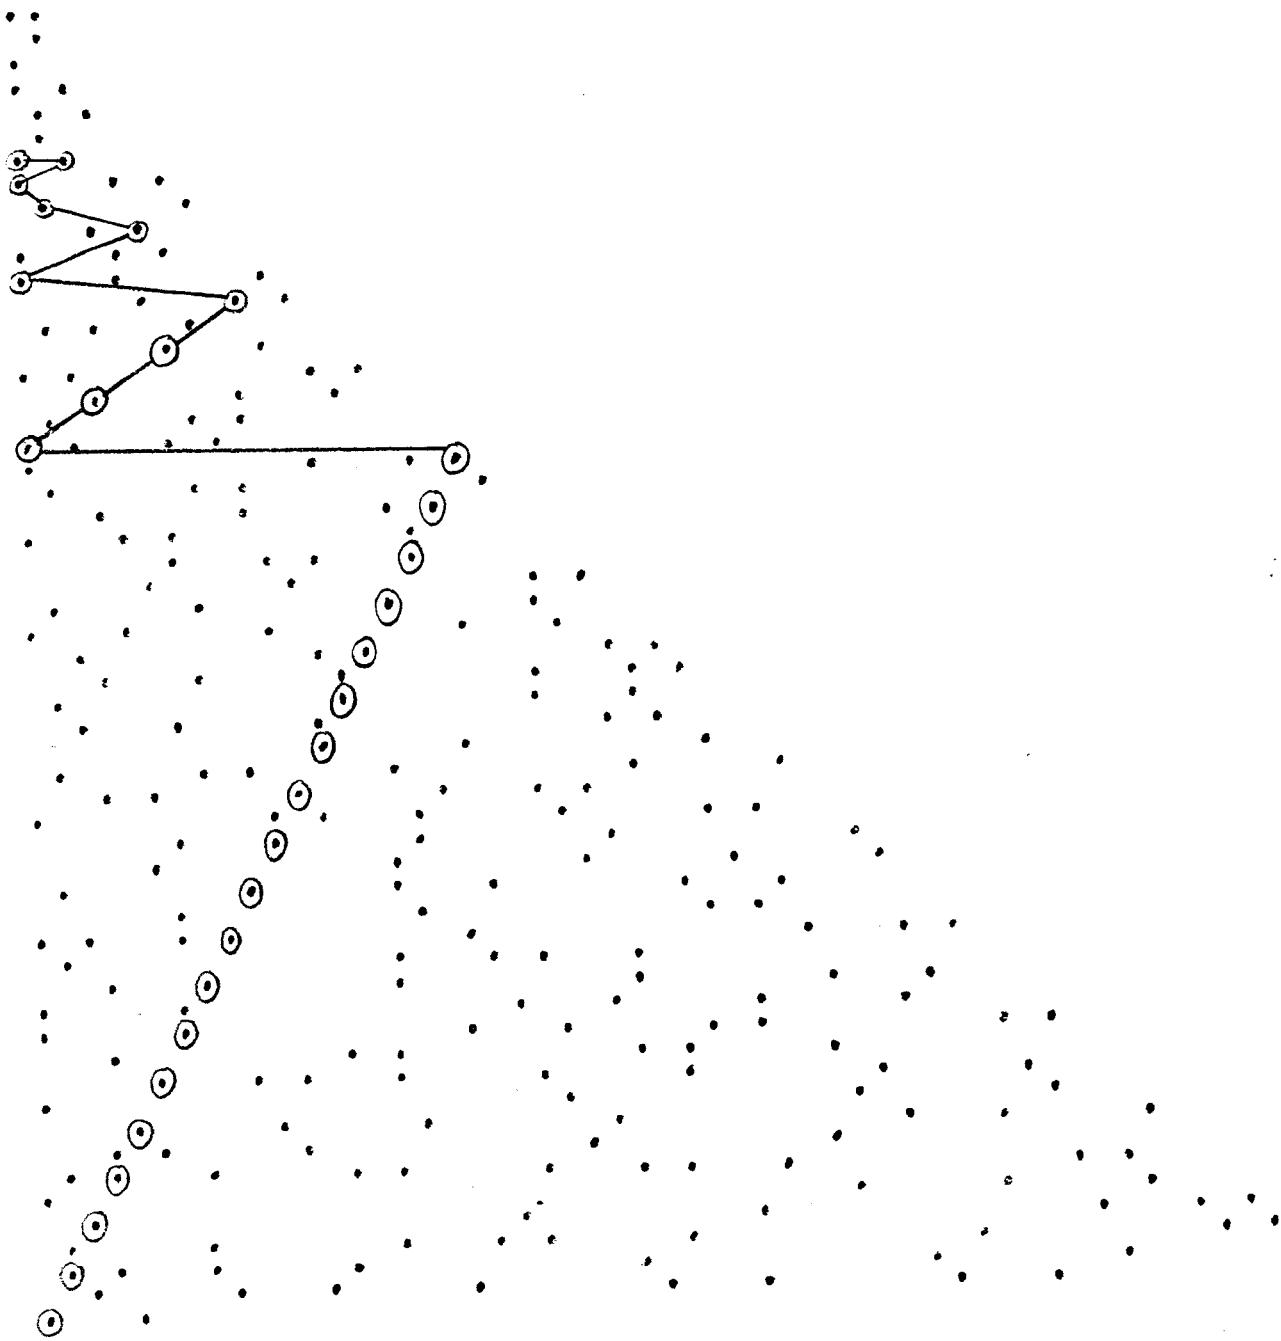

Figure 45.

More recently, though, I wondered what would appear if the unused area "northeast" of the triangular array could somehow be extended into. What meaning, if any, could be attached to the points projected to by continuing the straight lines into that unused portion of the graph? For example

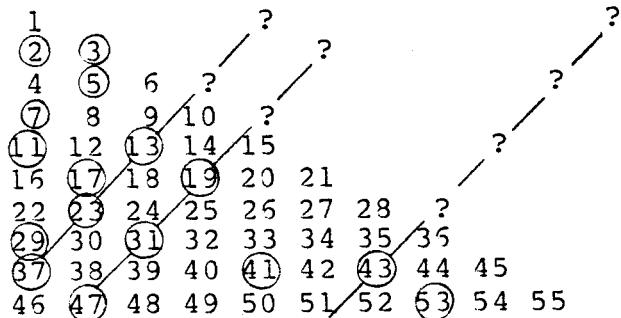

Figure 45.

Well, a natural approach to getting a handle on the spots designated by question marks would be to count over from the last spot on the same line of the triangular array. This would yield the following:

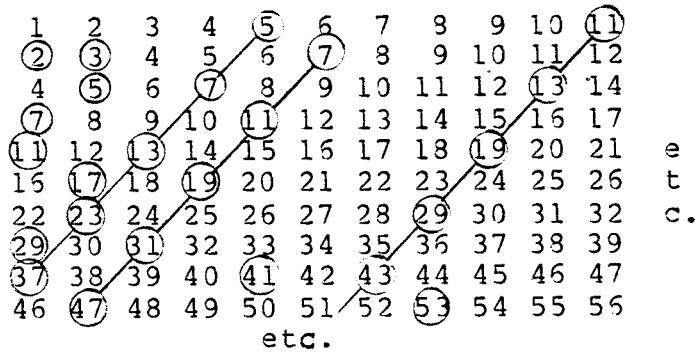

Figure 47.

Voila! The question-marked spots are the lower values of each given  $2x^2$  formula - all the lower values! (See figure 48.) What a satisfying result.

When the unused portion of the graph of the triangular array is fully extended into by counting across from the "hypotenuse" and all occurrences of primes are singled out as in figure 49, new patterns of primes, encompassing the whole graph, appear (See figures 50-54.).

Not only are there unbroken straight lines of "primes" but unbroken curves, too (See figures 55-58.).

Are any of these new patterns really new? No. Each

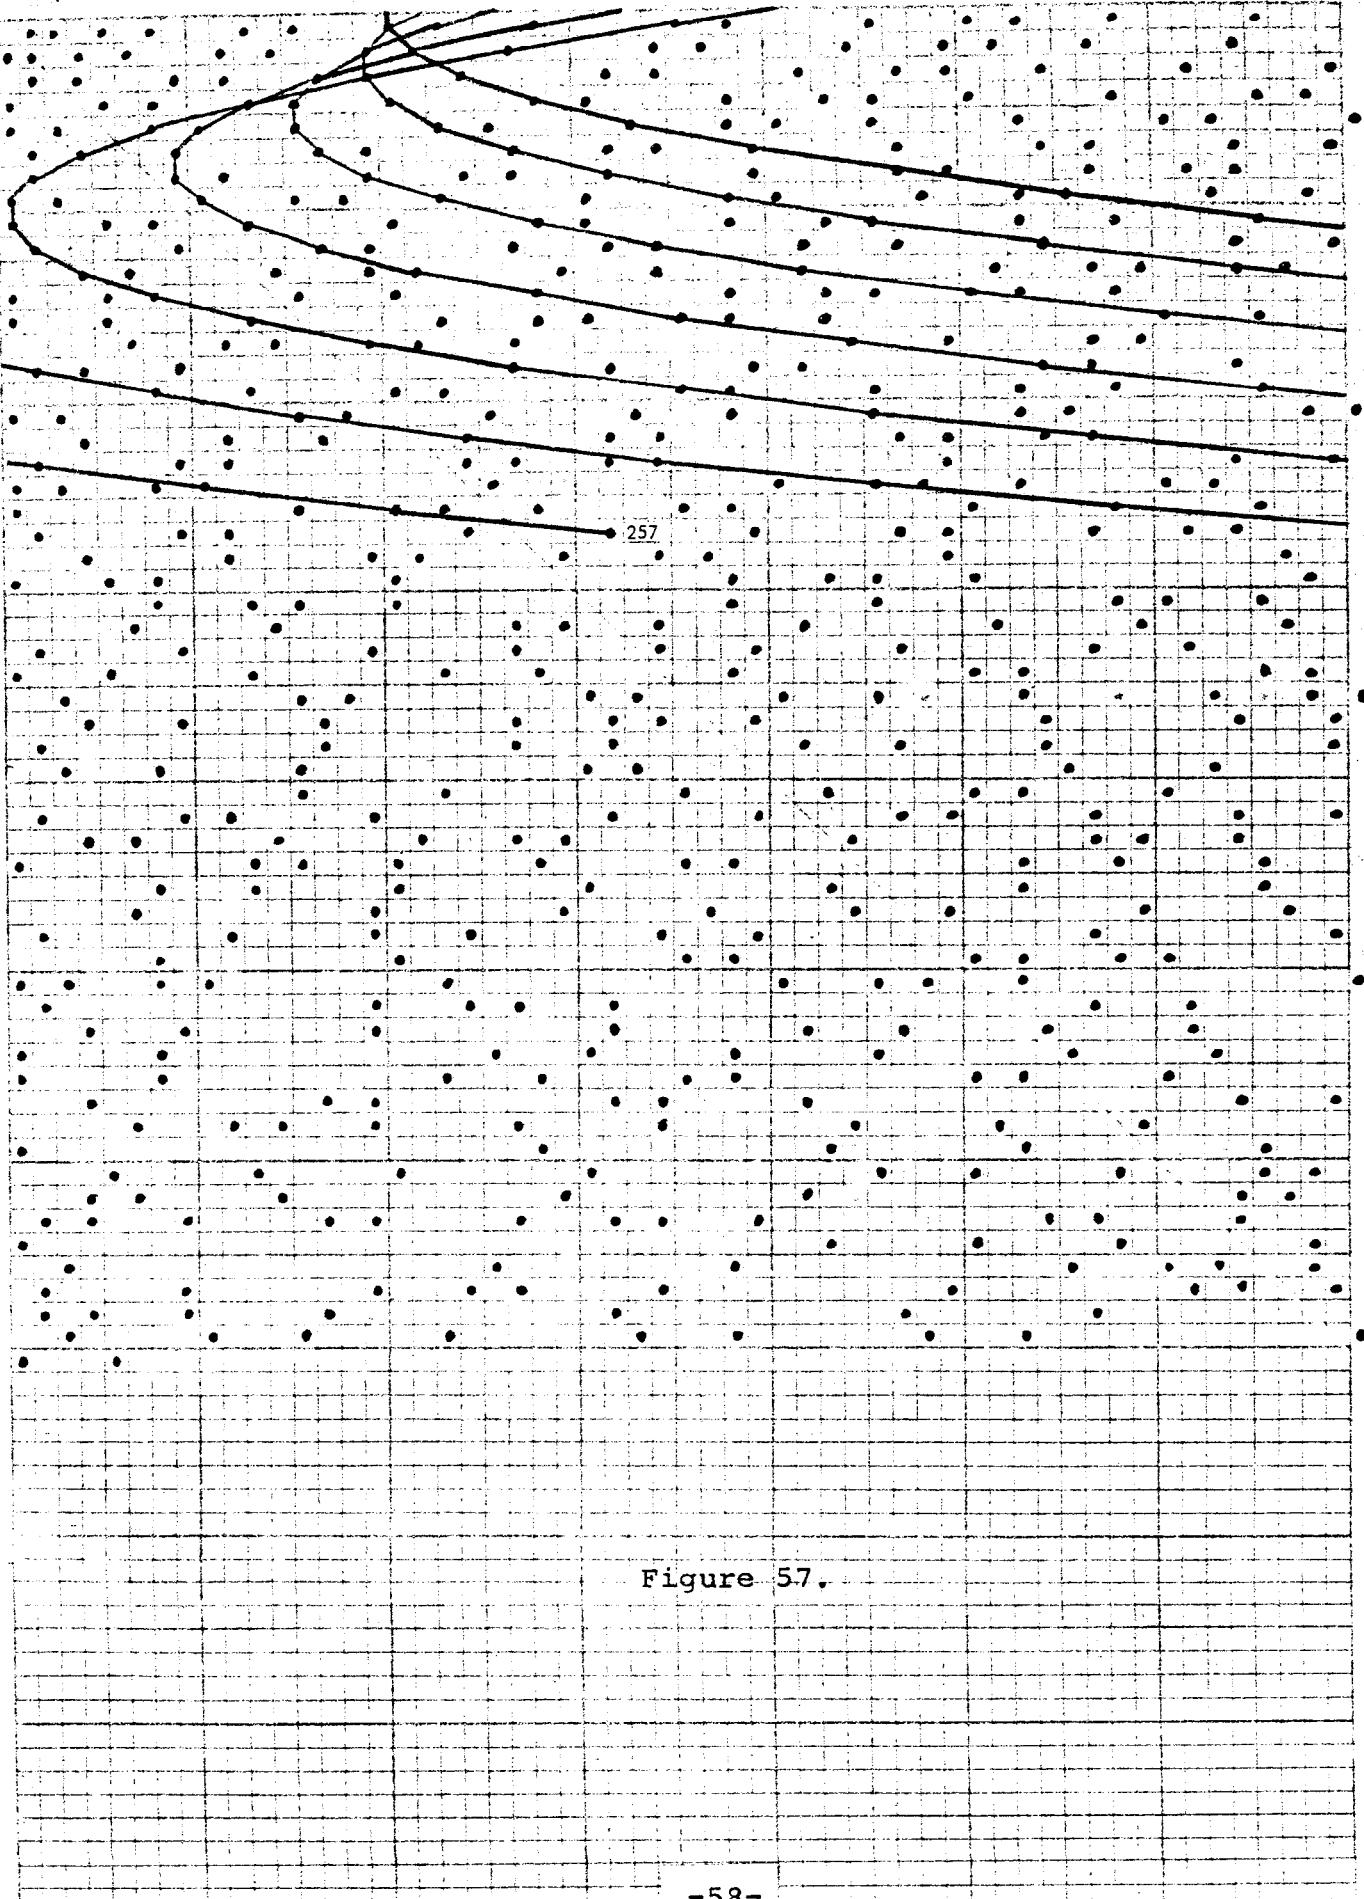

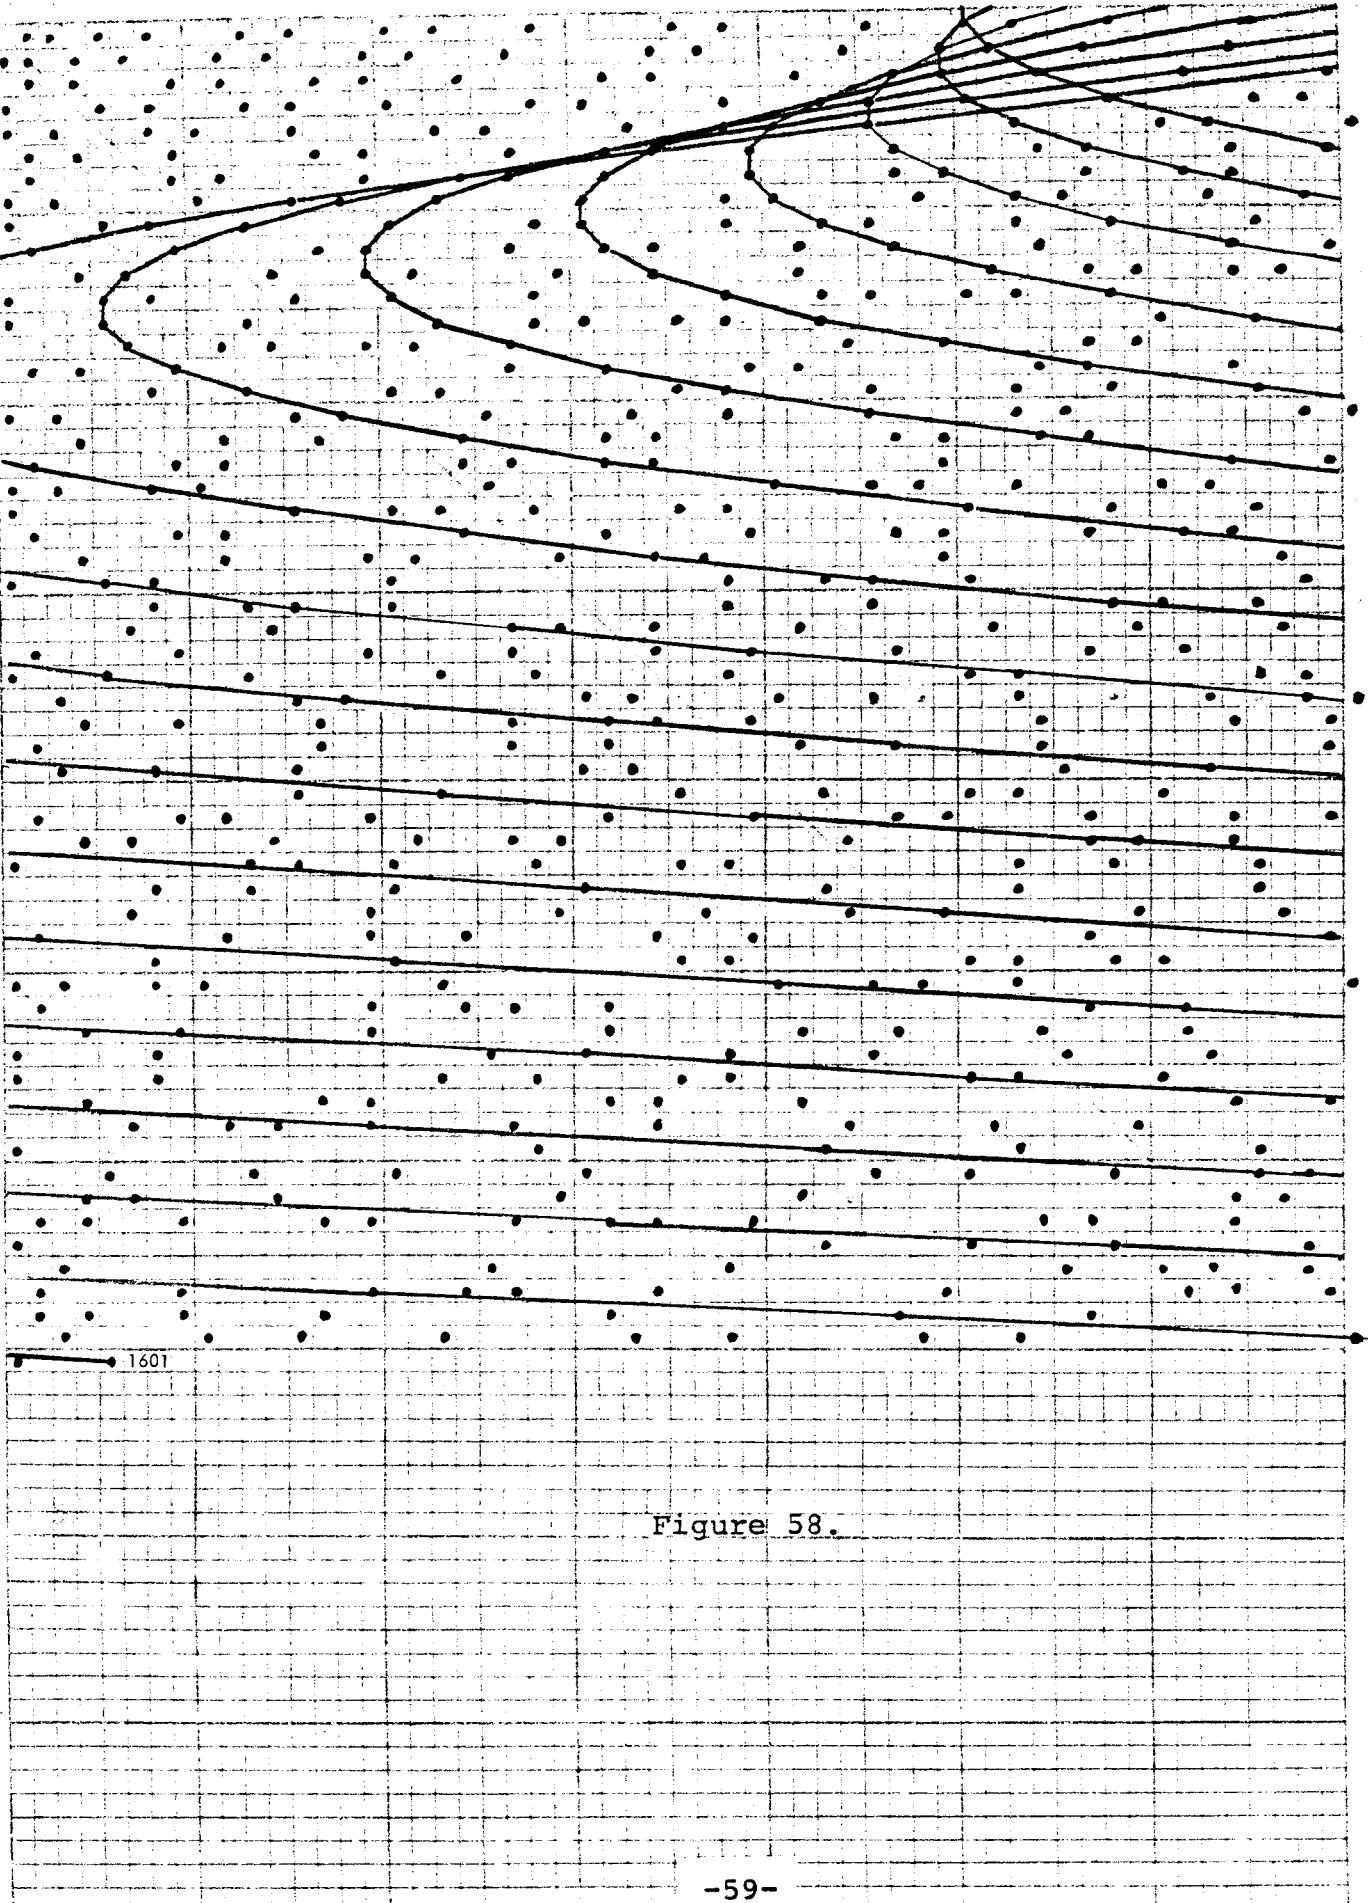

Figure 57.

new straight line is the same series as an original straight line, while each curve family belongs to its respective "design" (each  $x^2 + x$  sequence generates "the design"). The difference between the four  $x^2 + x$  "designs" is their displacement from the y-axis of the triangular array.

## 11. UNBROKEN PRIME RIBS

I was recently perusing a graph of the triangular array that I had made ten years ago, the one which had originally led me to extend  $x^2 + x + 41$  outside the triangular array. This graph contains each  $x^2 + x + c$  sequence easily identified by its own color ink, each represented as far as it gives primes for consecutive values of  $x$ .

Looking at the "ribs" of  $x^2 + x + 17$ , I decided to see if any primes would be hit if the "ribs" were extended beyond their existing limits, down the triangular array (See figure 59.).

Extending the rightmost rib down, the next spot it would hit is spot 323 (coordinates line 25, spot 23). 323 is not prime ( $323 = 17 \times 19$ ). Extending the rib any further takes it outside the triangular array.

Extending the center rib down, we first stop at 289, not a prime ( $289 = 17 \times 17$ ), then at a prime, 397. From there the rib hits another prime, 523. After that the rib leaves the triangular array.

Extending the left rib of  $x^2 + x + 17$  yields a surprise--all the spots extended to are primes: 359, 479, 617, and 773 (See figure 60.).

Wondering whether any other such prime ribs might lie waiting to be uncovered, I began testing some  $x^2 + x + 41$  downward ribs. I tested the five ribs indicated in figure 61 from left to right.

The first, third, and fifth ribs hit a non-prime right away. The second rib was a real tease, though. For the first eight spots extended to, a prime is the resident: 1847, 2297, 2797, 3347, 3947, 4597, 5297, and 5047. The next spot is not a prime, however:  $6847 = 41 \times 167$ .

The fourth rib hits only primes: 1933, 2393, 2903, 3463, 4073, 4733, 5443, 5203, 7013, and 7373.

Counting the four spots prior to 1933 in the fourth rib, 593, 853, 1163, and 1523 (not tested since we already know they're prime, being in  $x^2 + x + 41$  where  $-1 < x < 40$ ), the rib has fourteen spots, all of which are prime. (See figure 62.)

Figure 59.

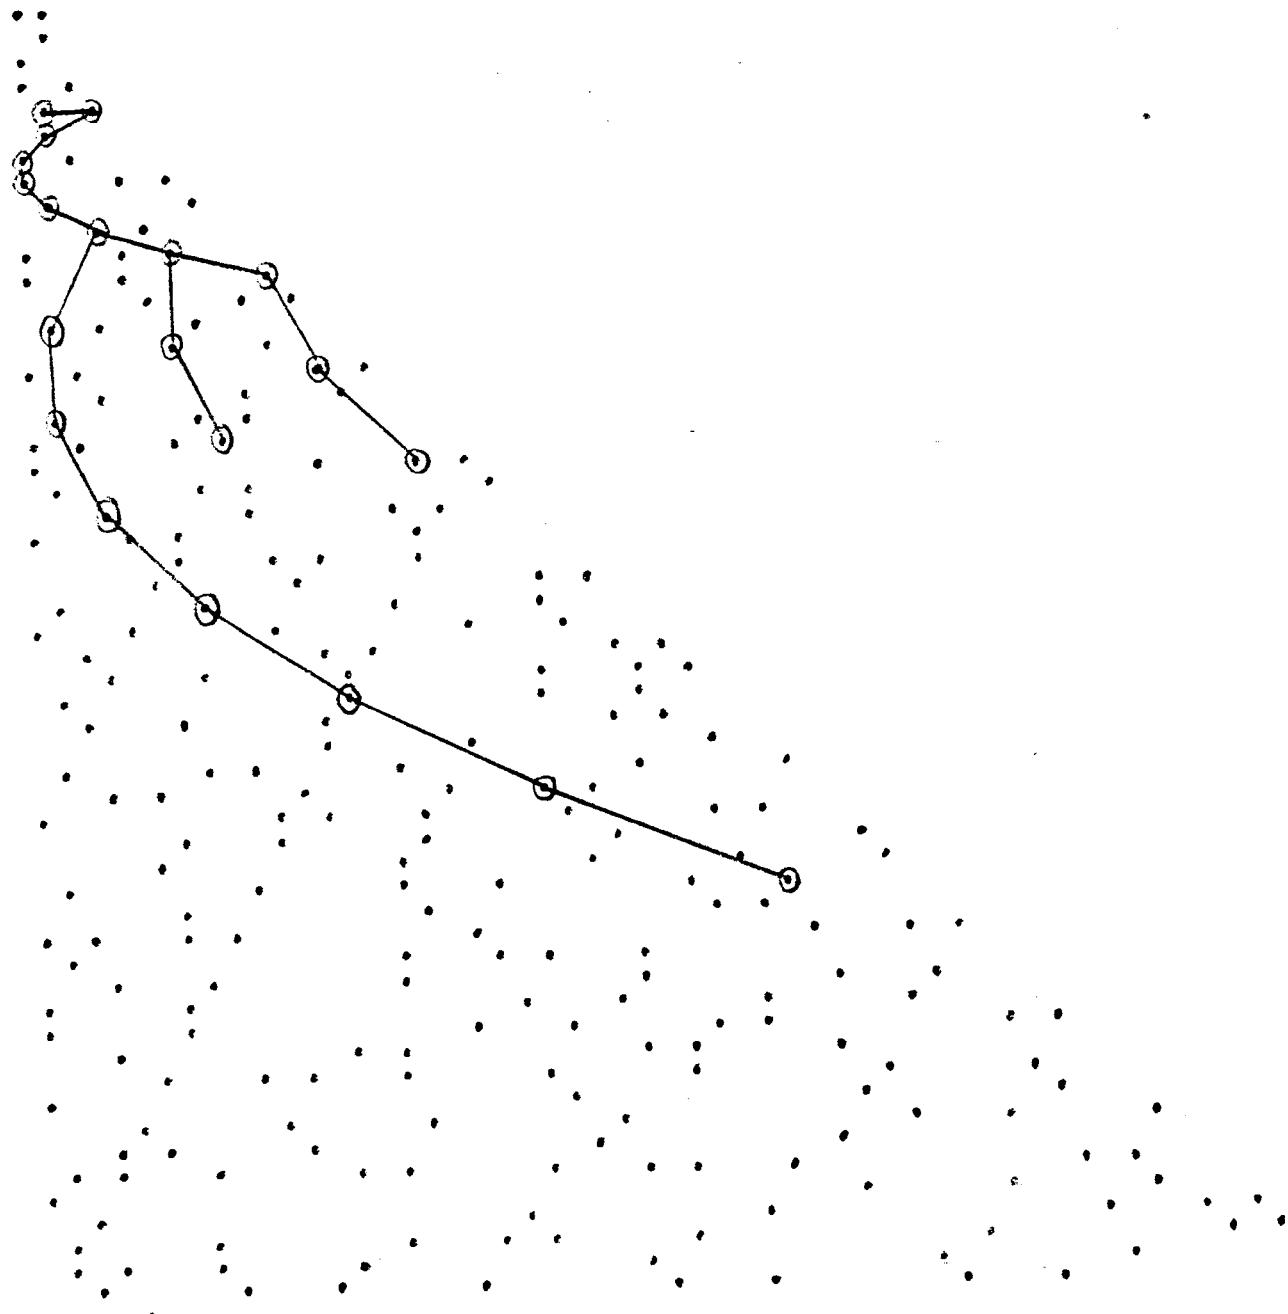

Figure 60.

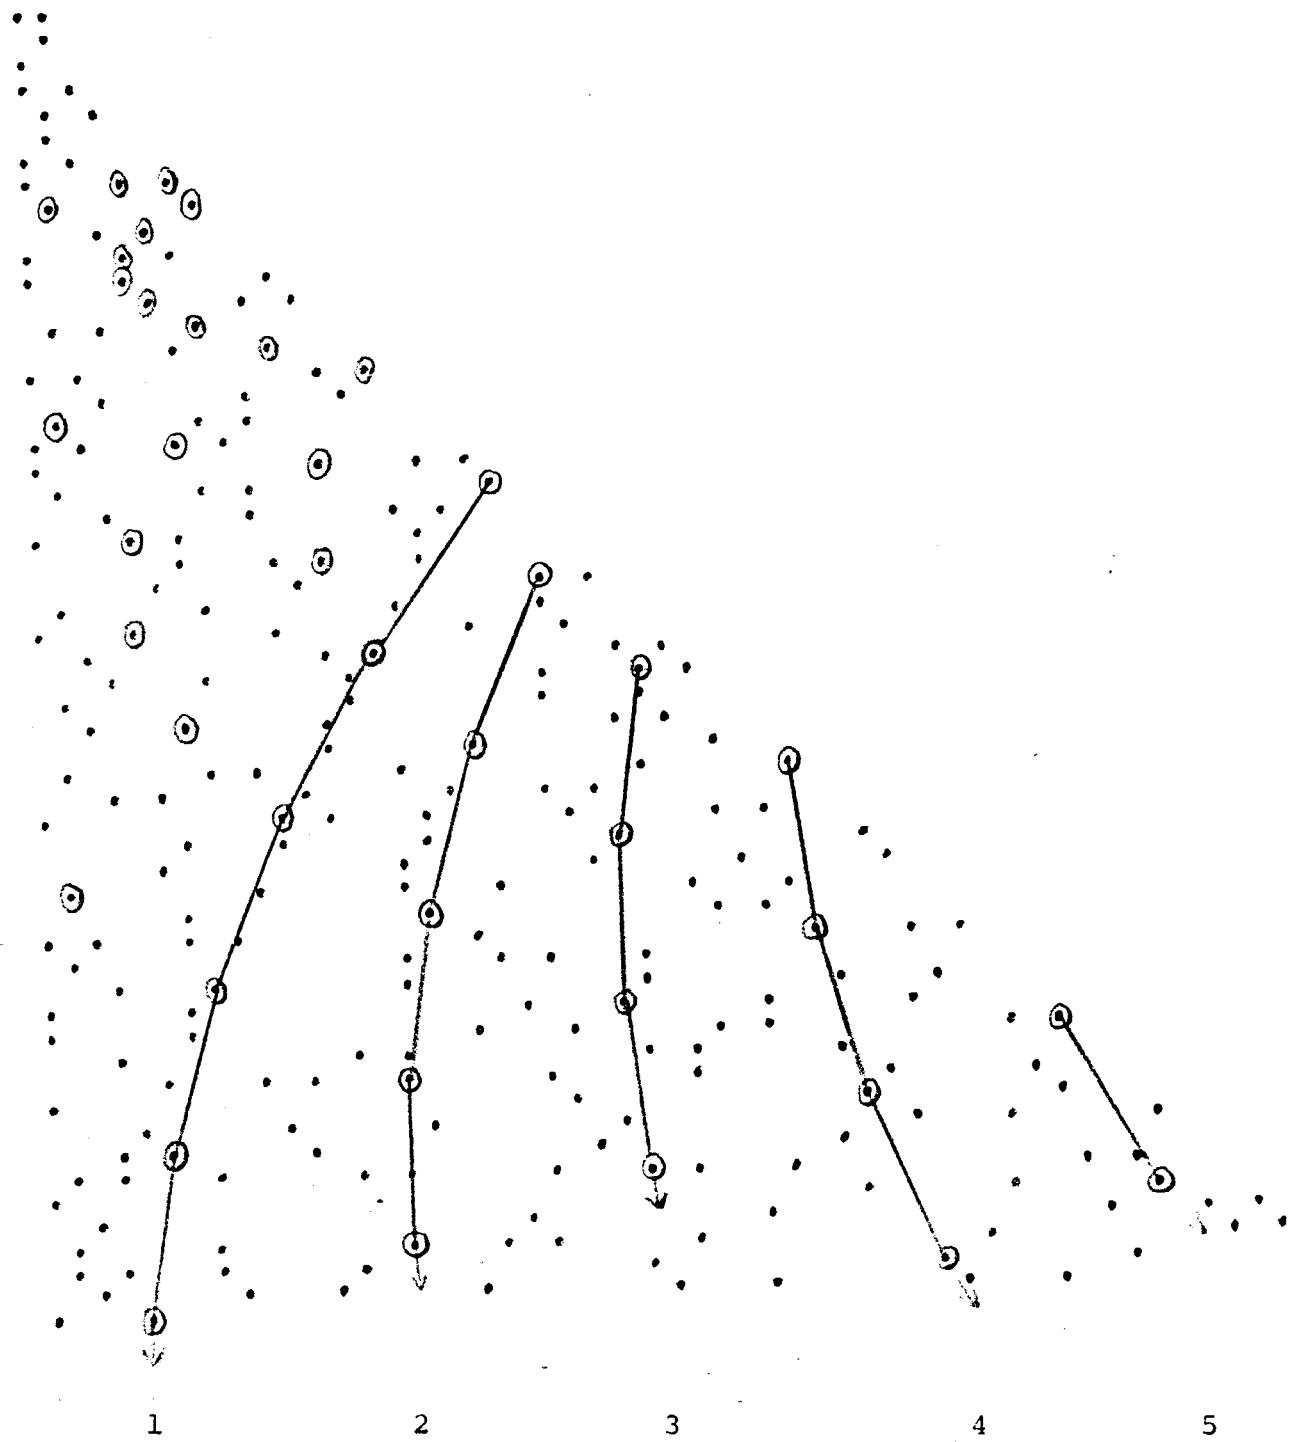

Figure 61.

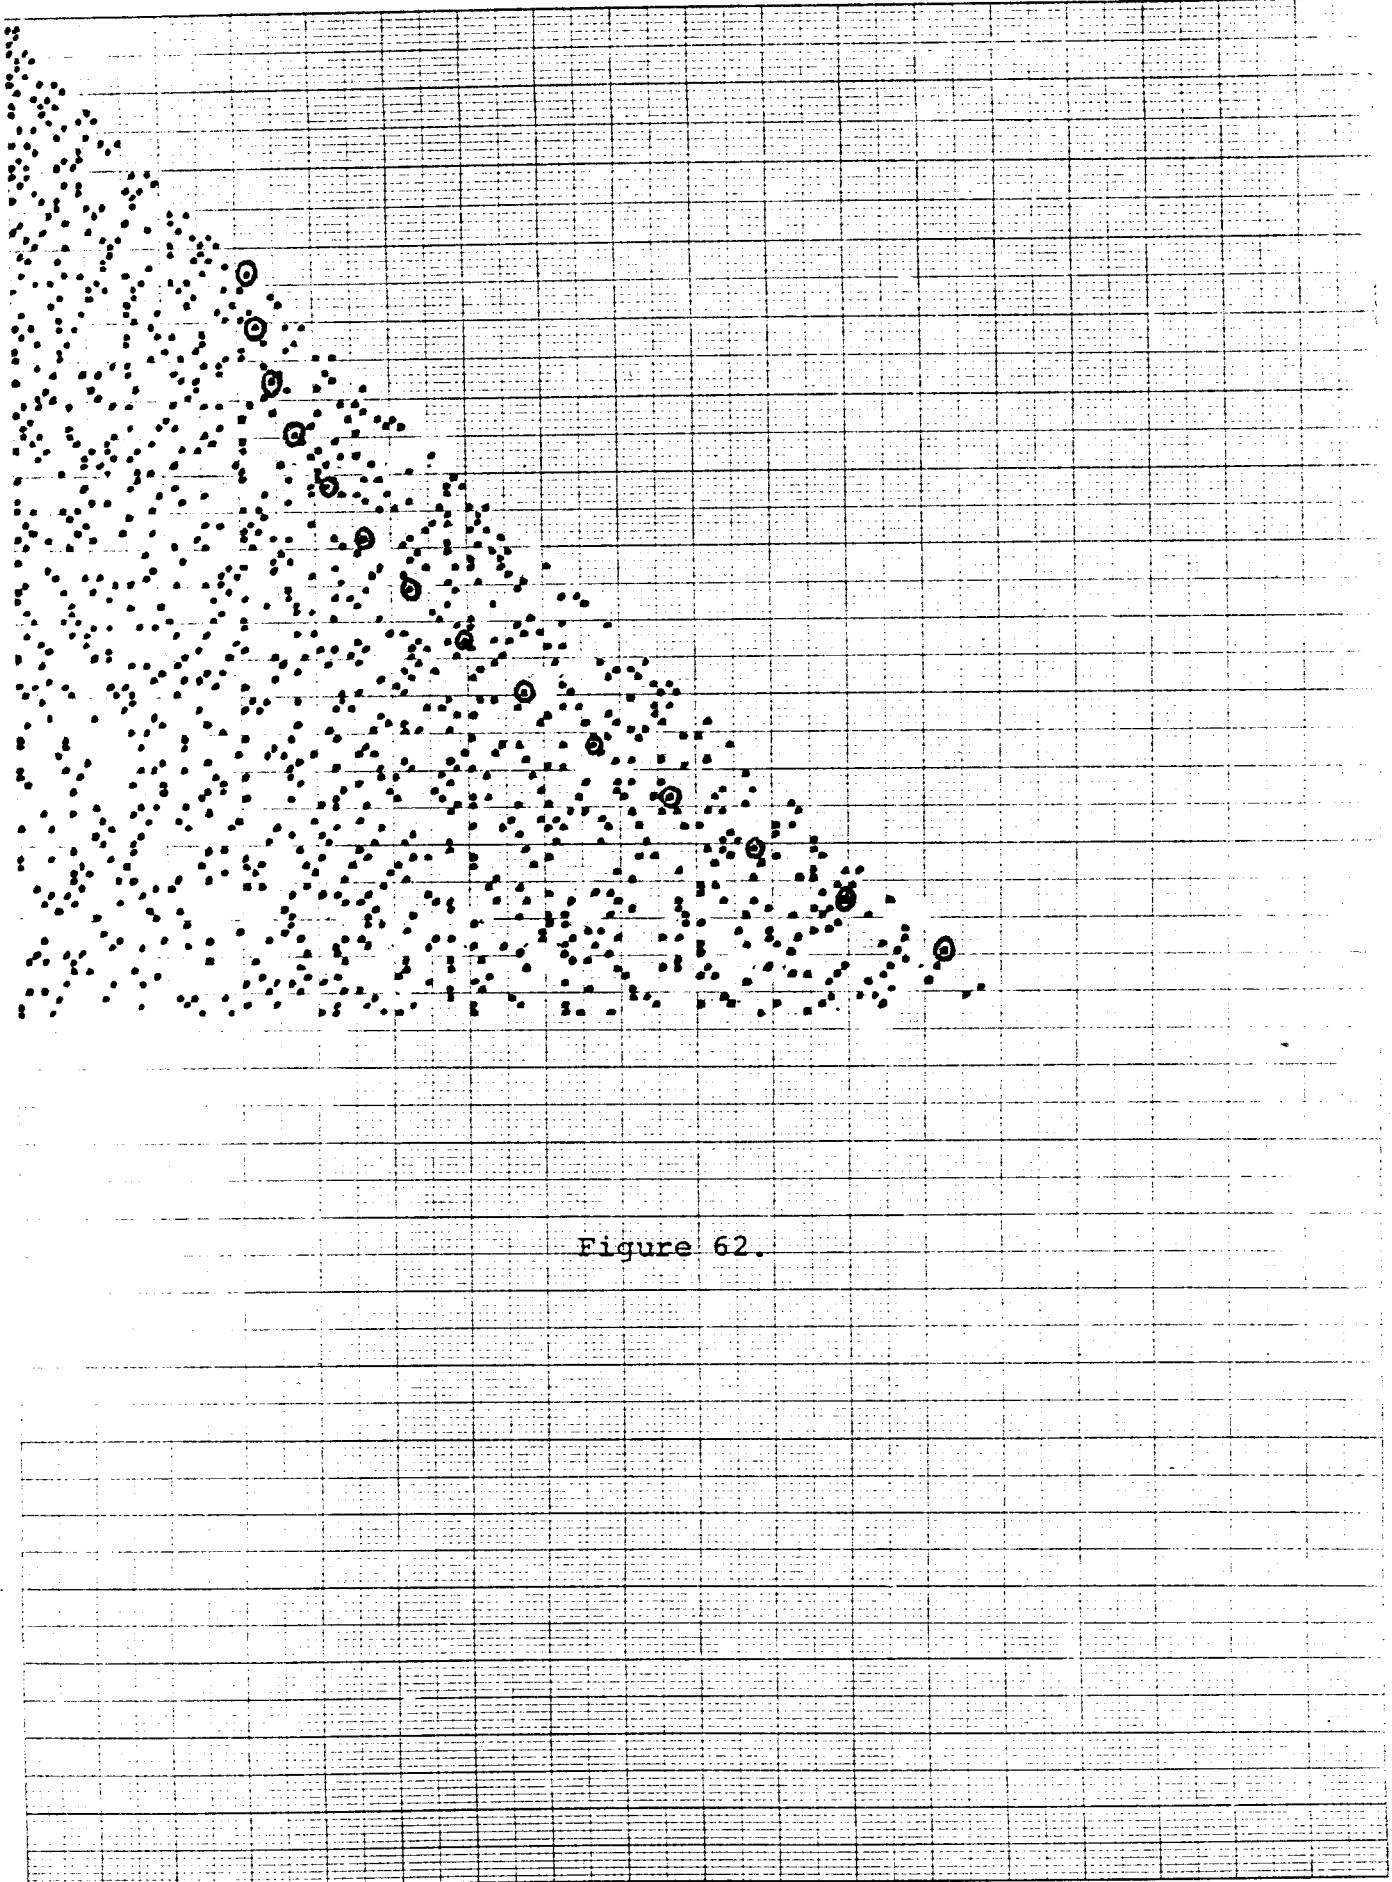

Figure 62.

Perhaps there are more all-prime ribs further down the array - who knows?

## 12. THE OTHER ARRAY AND THE OTHER FOUR LINES

Another more recent tack taken has been experimentation with variations on the triangular array. For example, what happens to the configuration of primes when we count

1	2				
3	4	5	6		
7	8	9	10	11	12
etc.					

Figure 63.

Are there new patterns, like straight lines, to be found? Are there perhaps new sequences and thus formulas lying hidden there, waiting for us to find the right key to unlock these secrets? The answers are, respectively, yes and no.

There are new patterns - in fact, four parallel straight lines of primes - to be seen. The sequences and their associated formulas are not new, however. Indeed, they are our old friends, the four  $x^2$  sequences (See figure 64.).

Trying yet another counting variation,

1				
2	3	4		
5	6	7	8	9
etc.				

Figure 65.

the same lines appear, but slanted. This time they look just like the lines of the original triangular array (See figure 66.).

When these four lines are extended into the unused "northeast" area of the graph, the spots projected to also correspond to all the lower values in each given sequence (See figure 67.).

## 13. $2x^2 + 2x$ ON THE OTHER ARRAY

I decided to see what design would appear, if any, like the curving one made by  $x^2 + x$  on the original triangular array, when I plotted  $2x^2 + 2x$  on the new triangular array and then extended the curves beyond the new array. The new

"design" turned out to be very similar to the original one, the only difference being the format and spacing of curve family members (See figure 68.).

#### 14. "DESIGN" - MULTABLE PARALLELS

There is an interesting resemblance between two unrelated curve families: the right void adjacent curve family of the new "design" (when viewed with the void at the bottom) and a nested family of curves in a multiplication table that I have devised. The multiplication table is shown in figure 59. / call it the multable parallel

In this table the x-values are products. The factors are a) the y-value and b) the number of dots over from the y-axis. For example, moving horizontally to the right from the y-axis at height = 11, we first encounter a dot at 11 on the x-axis, the second dot across is at 22 on the x-axis, and so on.

By arranging the multiplication table in this manner, prime numbers appear as empty vertical columns between the x-axis and the top diagonal on the graph. (See figure 70.)

When this graph is viewed from the right edge, looking toward the apex at the origin, there appear nested curves of dots as in figure 71.

One is first struck by the fact that all the dots in the table belong to one curve or another in the family (See figure 72.). So all composite (non-prime) numbers fall in these curves. It turns out that every other curve in the family, each curve with two dots at its vertex rather than only one, consists solely of even numbers (remembering that each dot represents a product). That being the case, only the one-dot-vertex curves (again, every other curve) genuinely eliminate odd candidates for primality, the candidates more difficult to crack at a glance.

These odd-depositing curves are of the format depicted in figure 73. The vertex is at a perfect square. The next two dots are over one and up one, the next two dots are over one and up three, the next two are over one and up five, and so on.

The spacing between family members is the distance between successive curve vertexes: 1, 3, 5, 7, ... (See figure 74.).

The new void adjacent families have members with a single dot vertex as well. In fact, these curves are of the same exact form as those of the multiplication table: vertex, two dots one over and one up, two dots one more over and three up, two dots one more over and five up, and so on.

Figure 68.

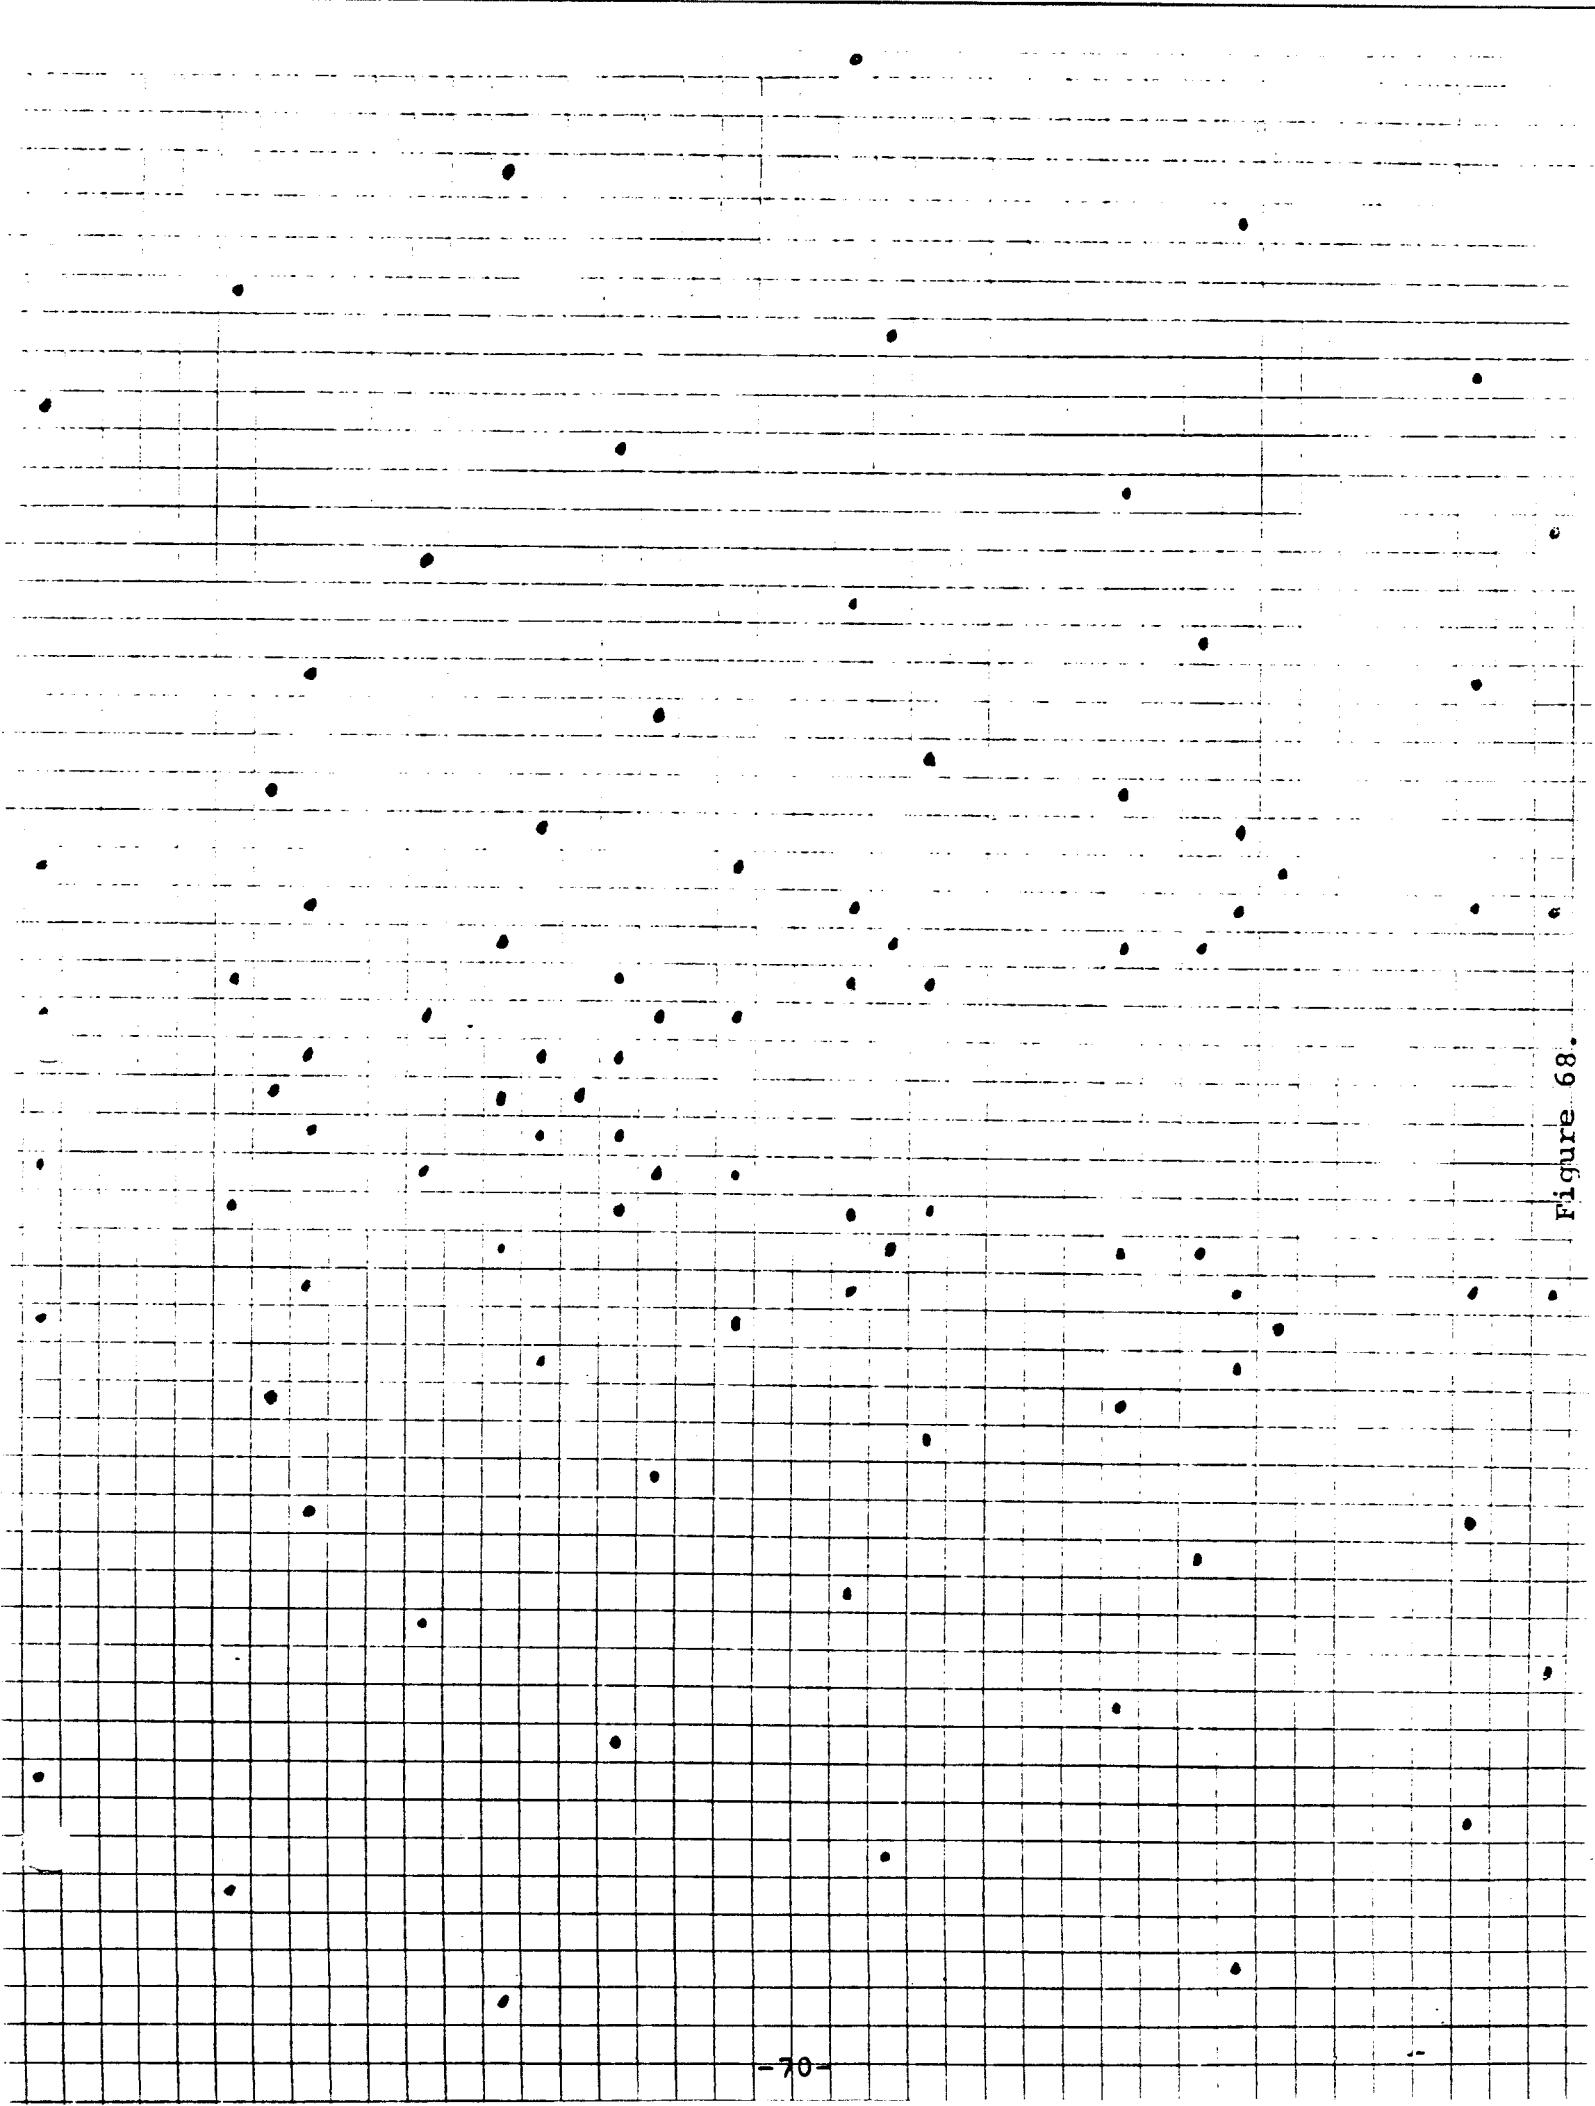

Figure 69.

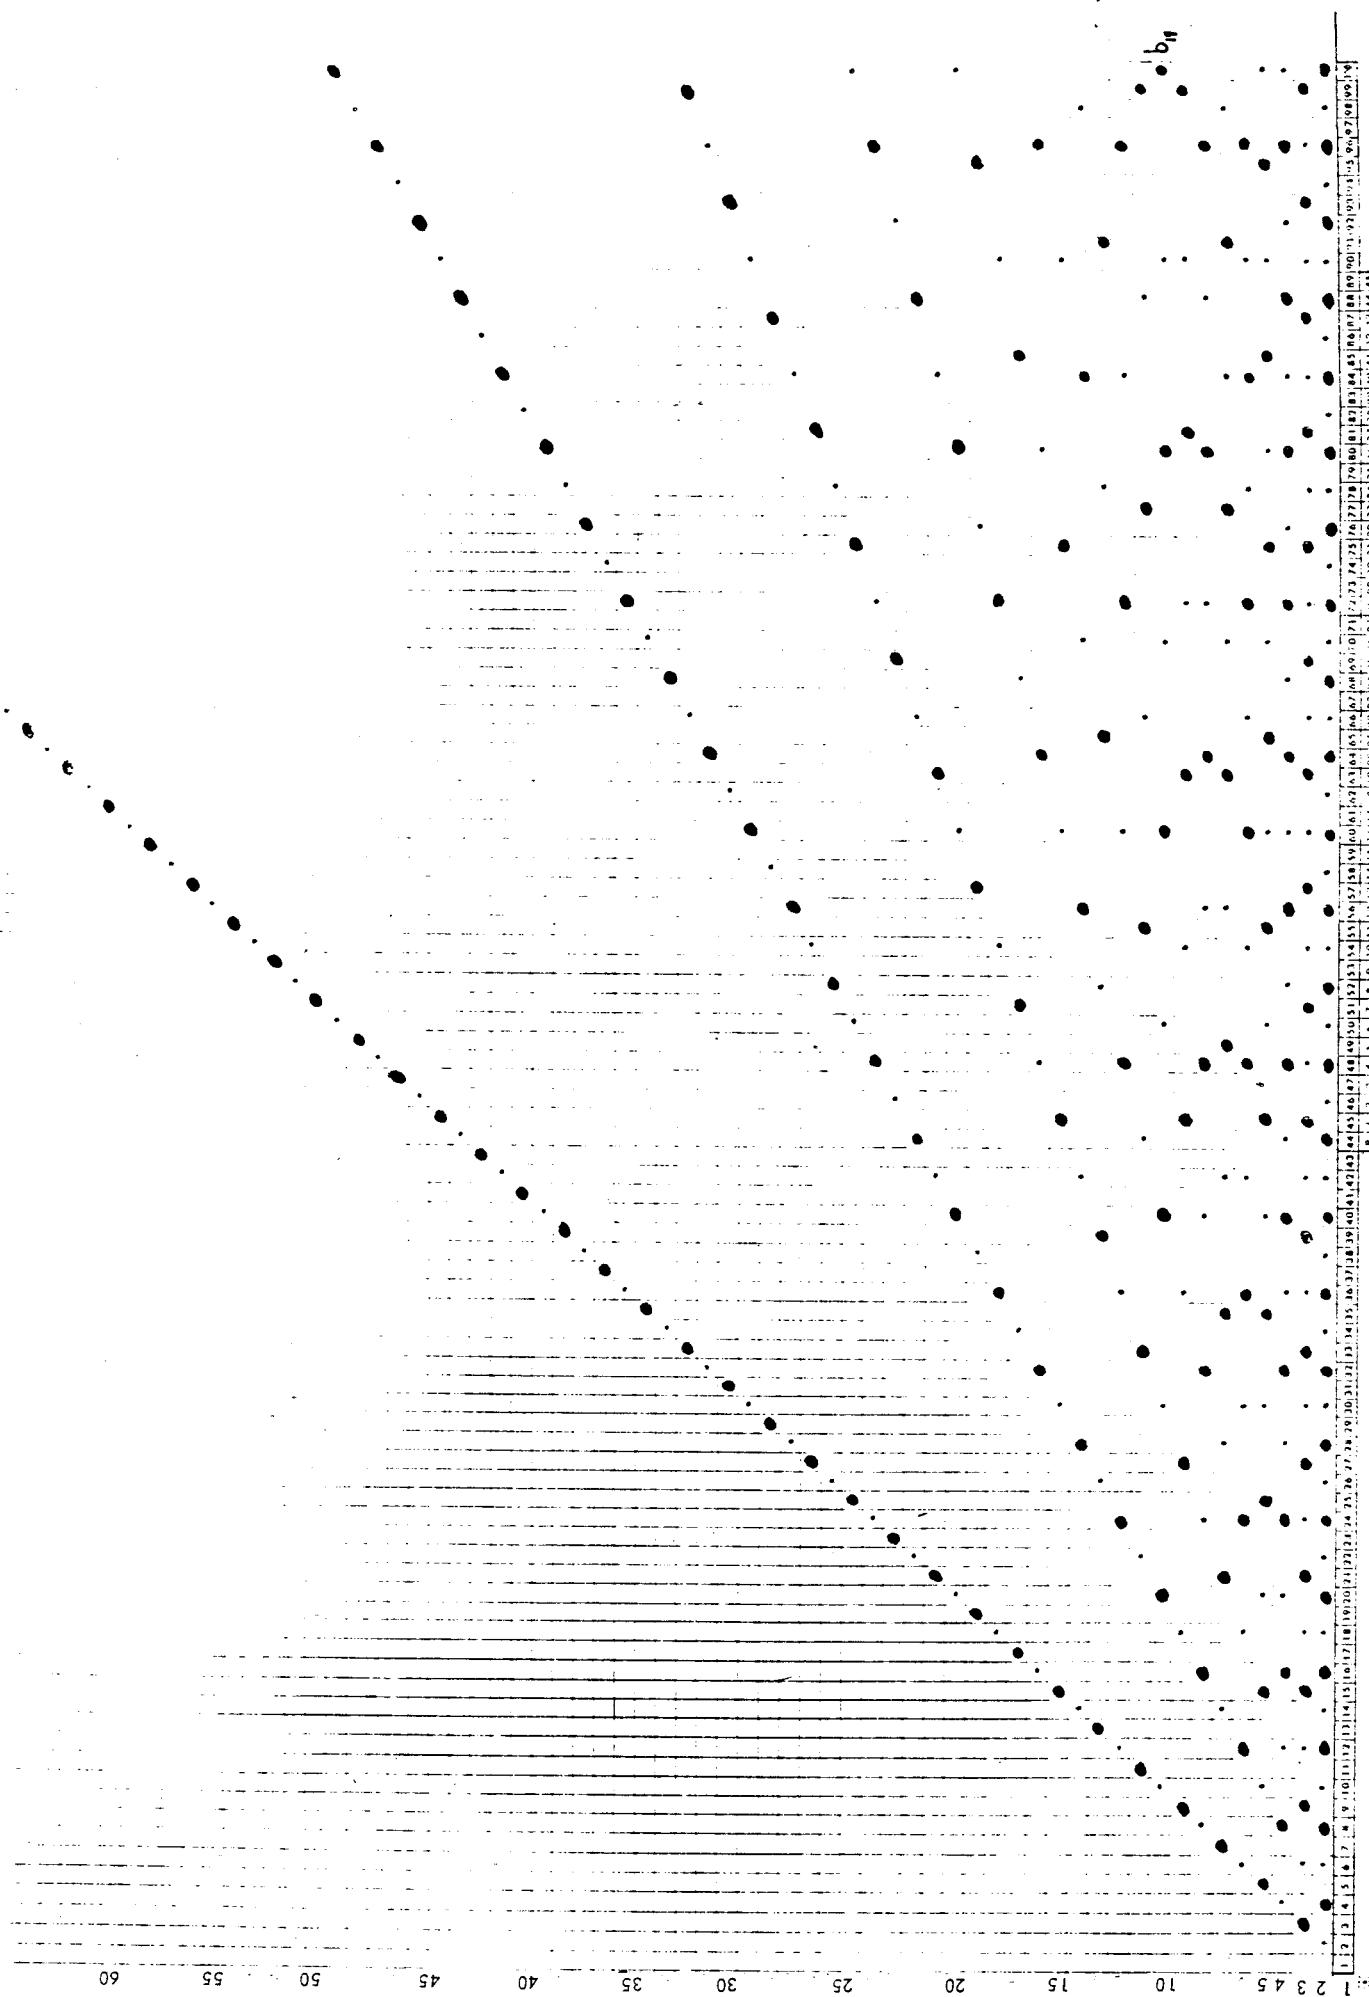

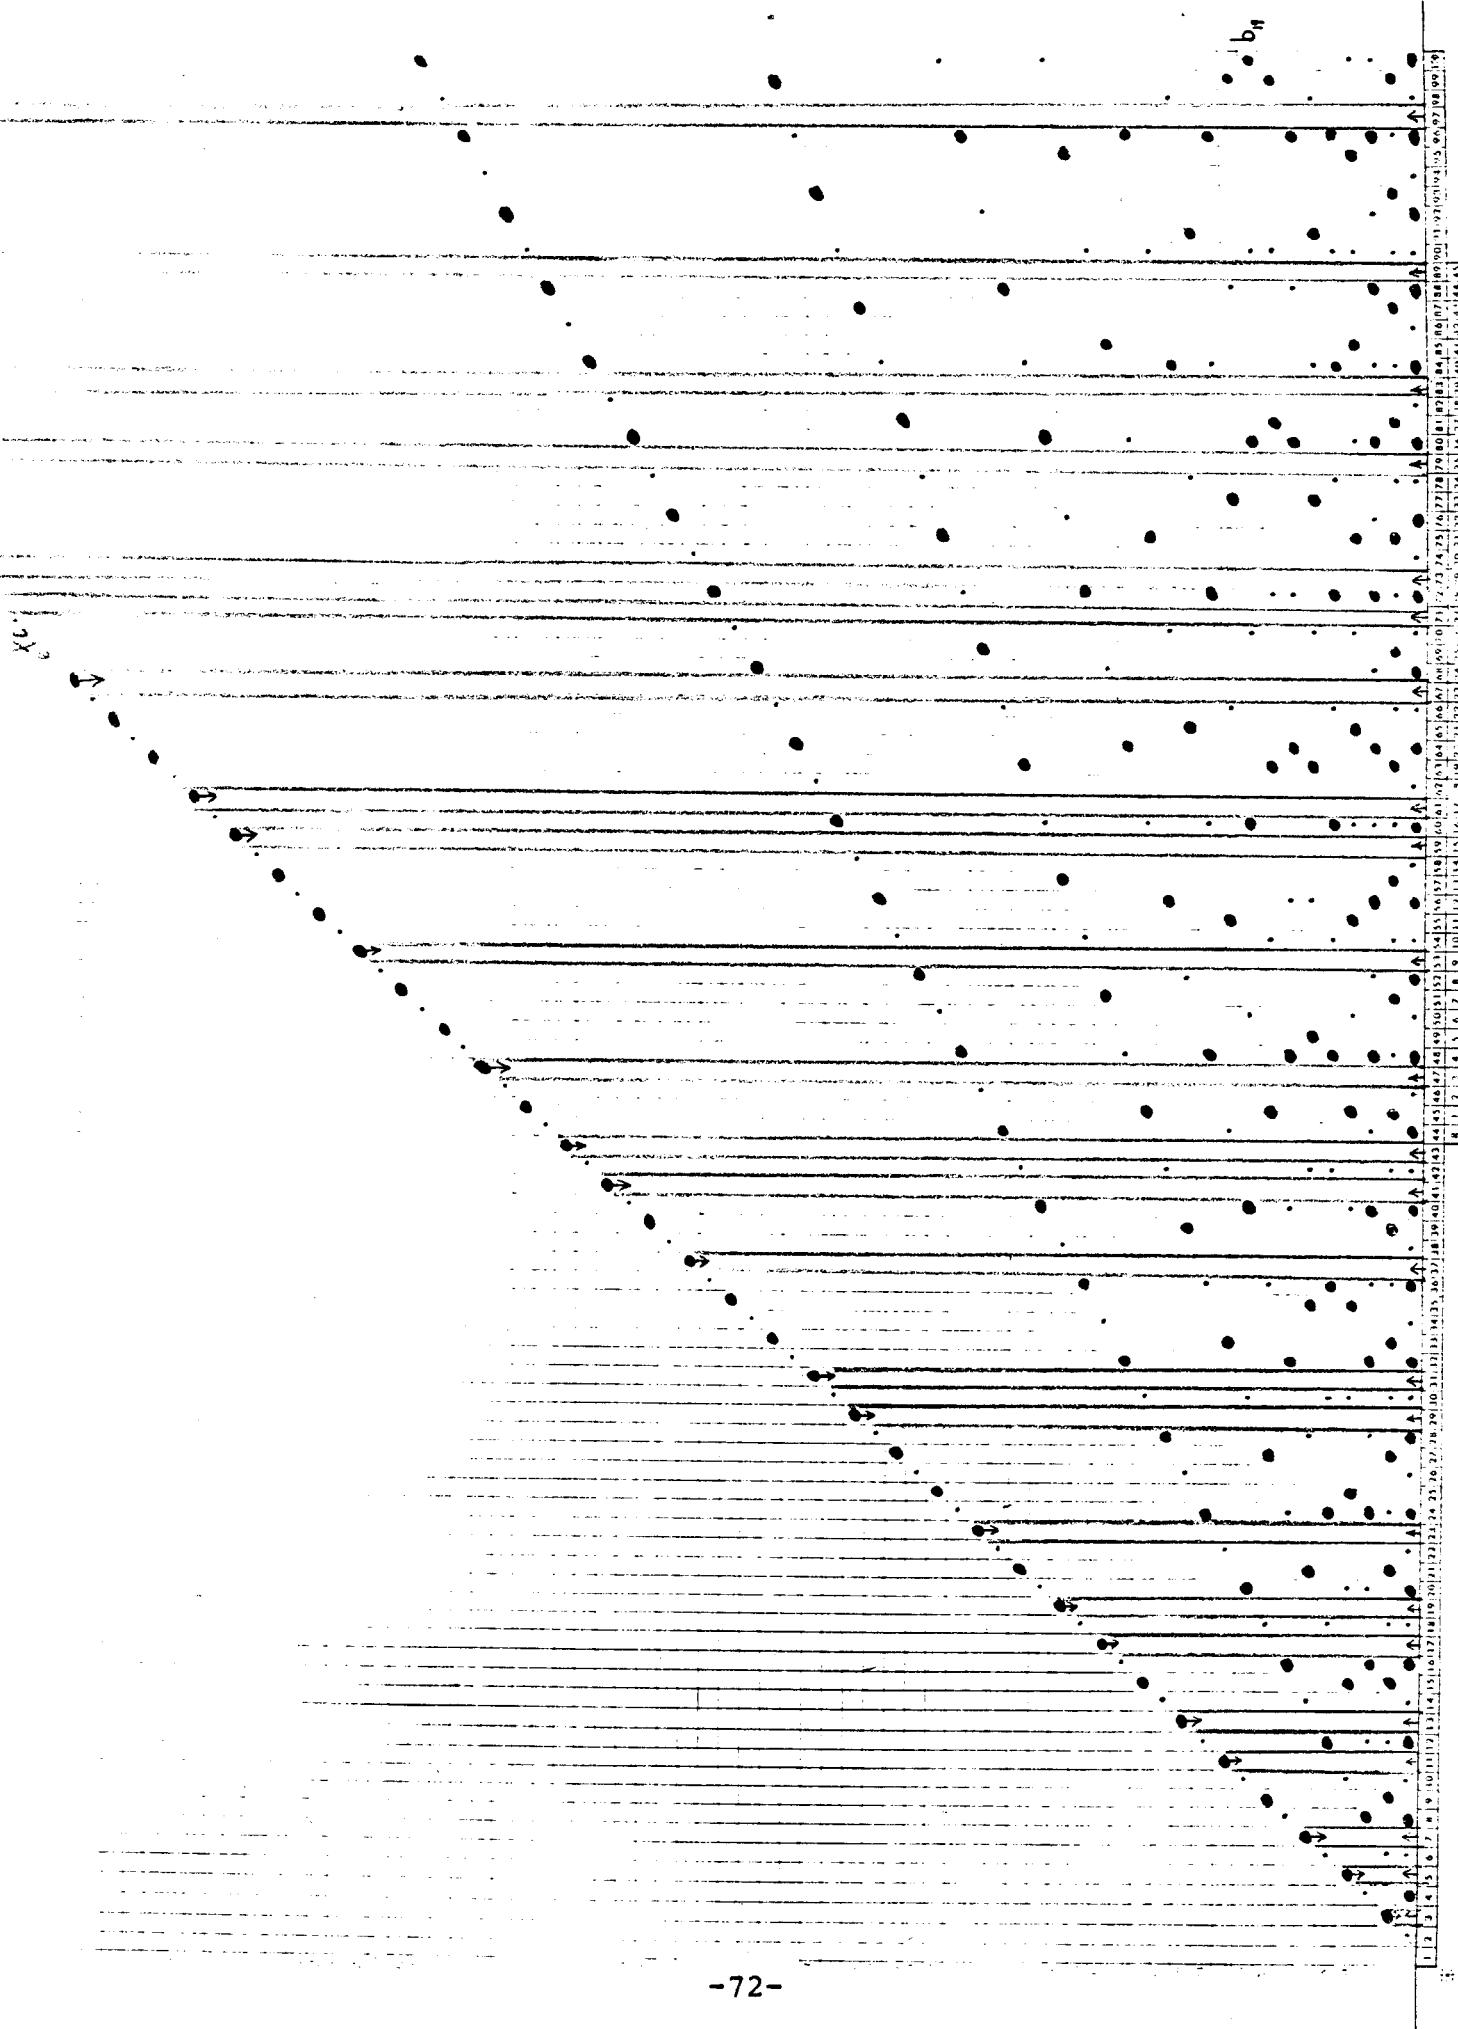

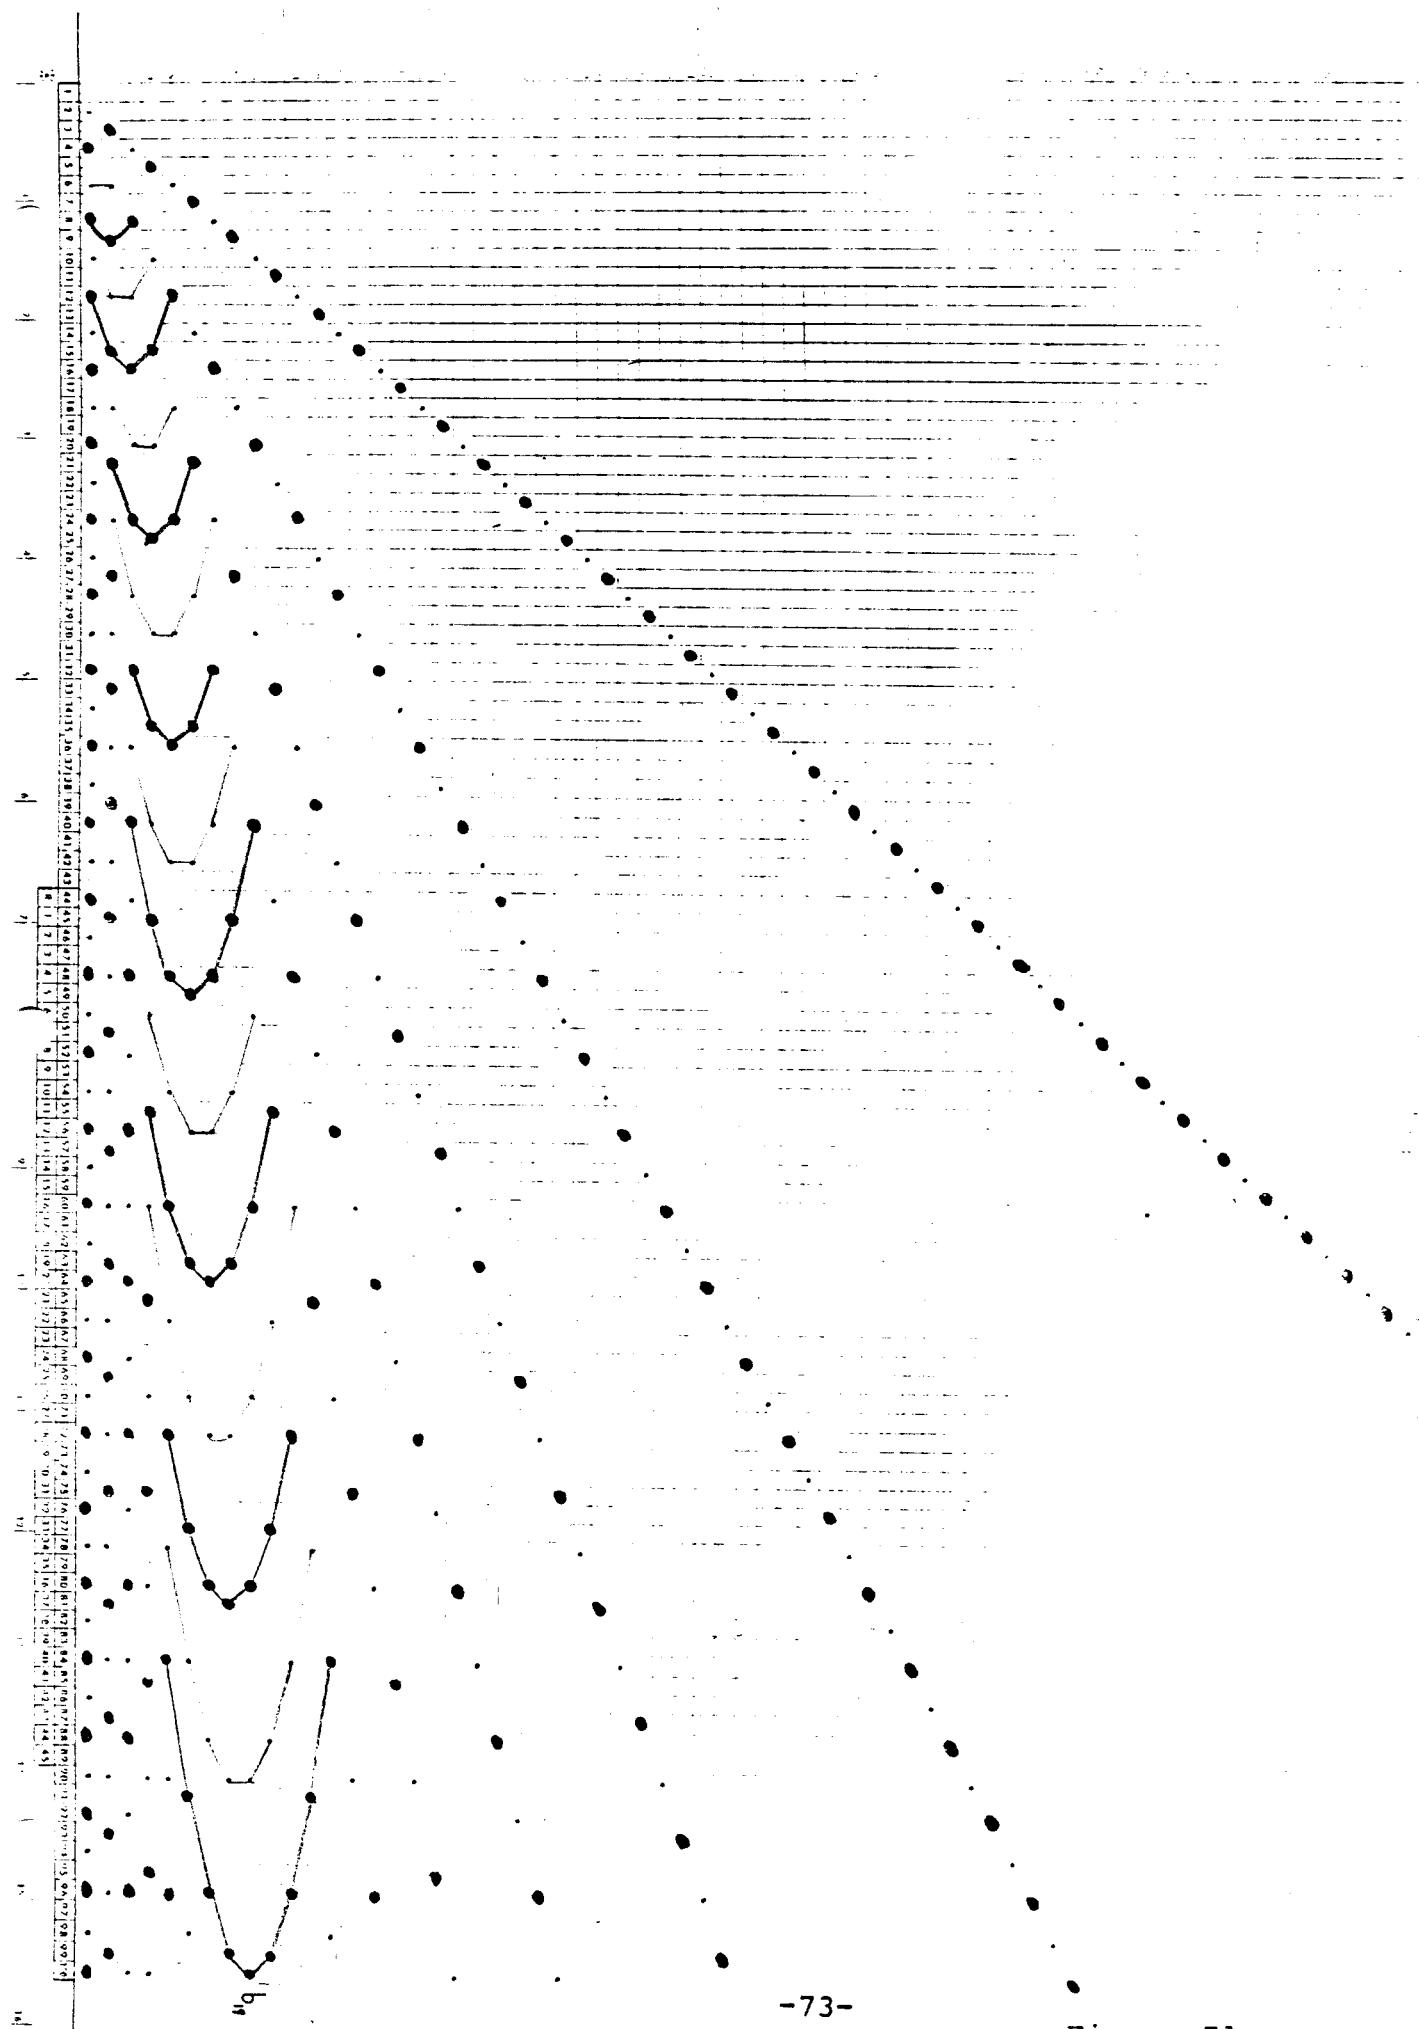

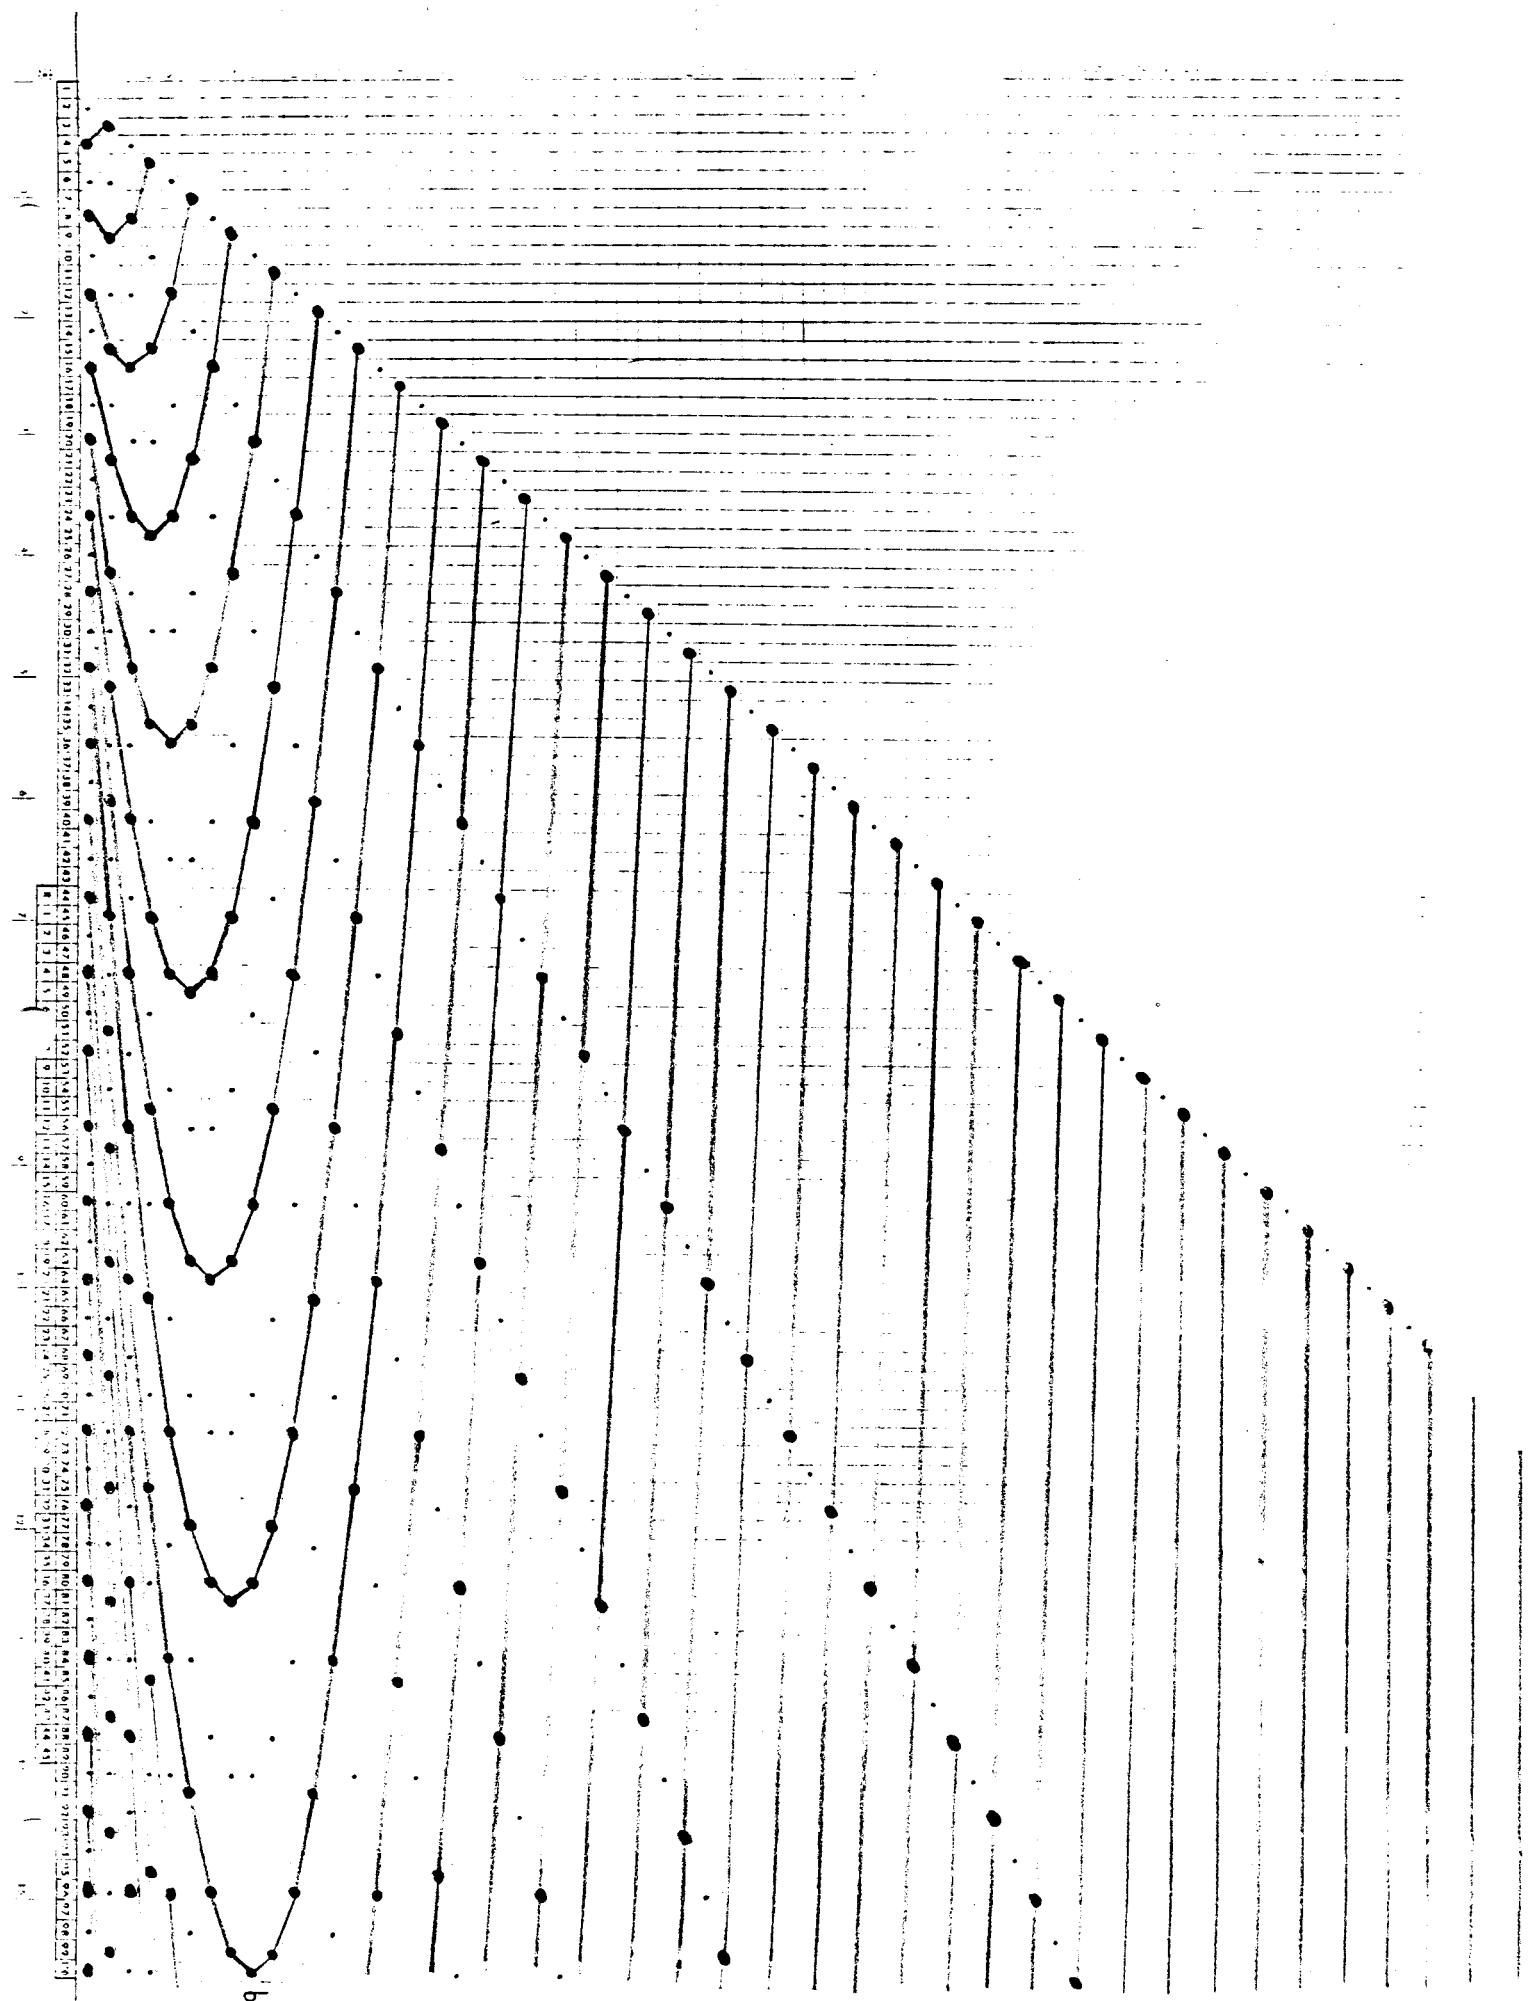

Figure 70.

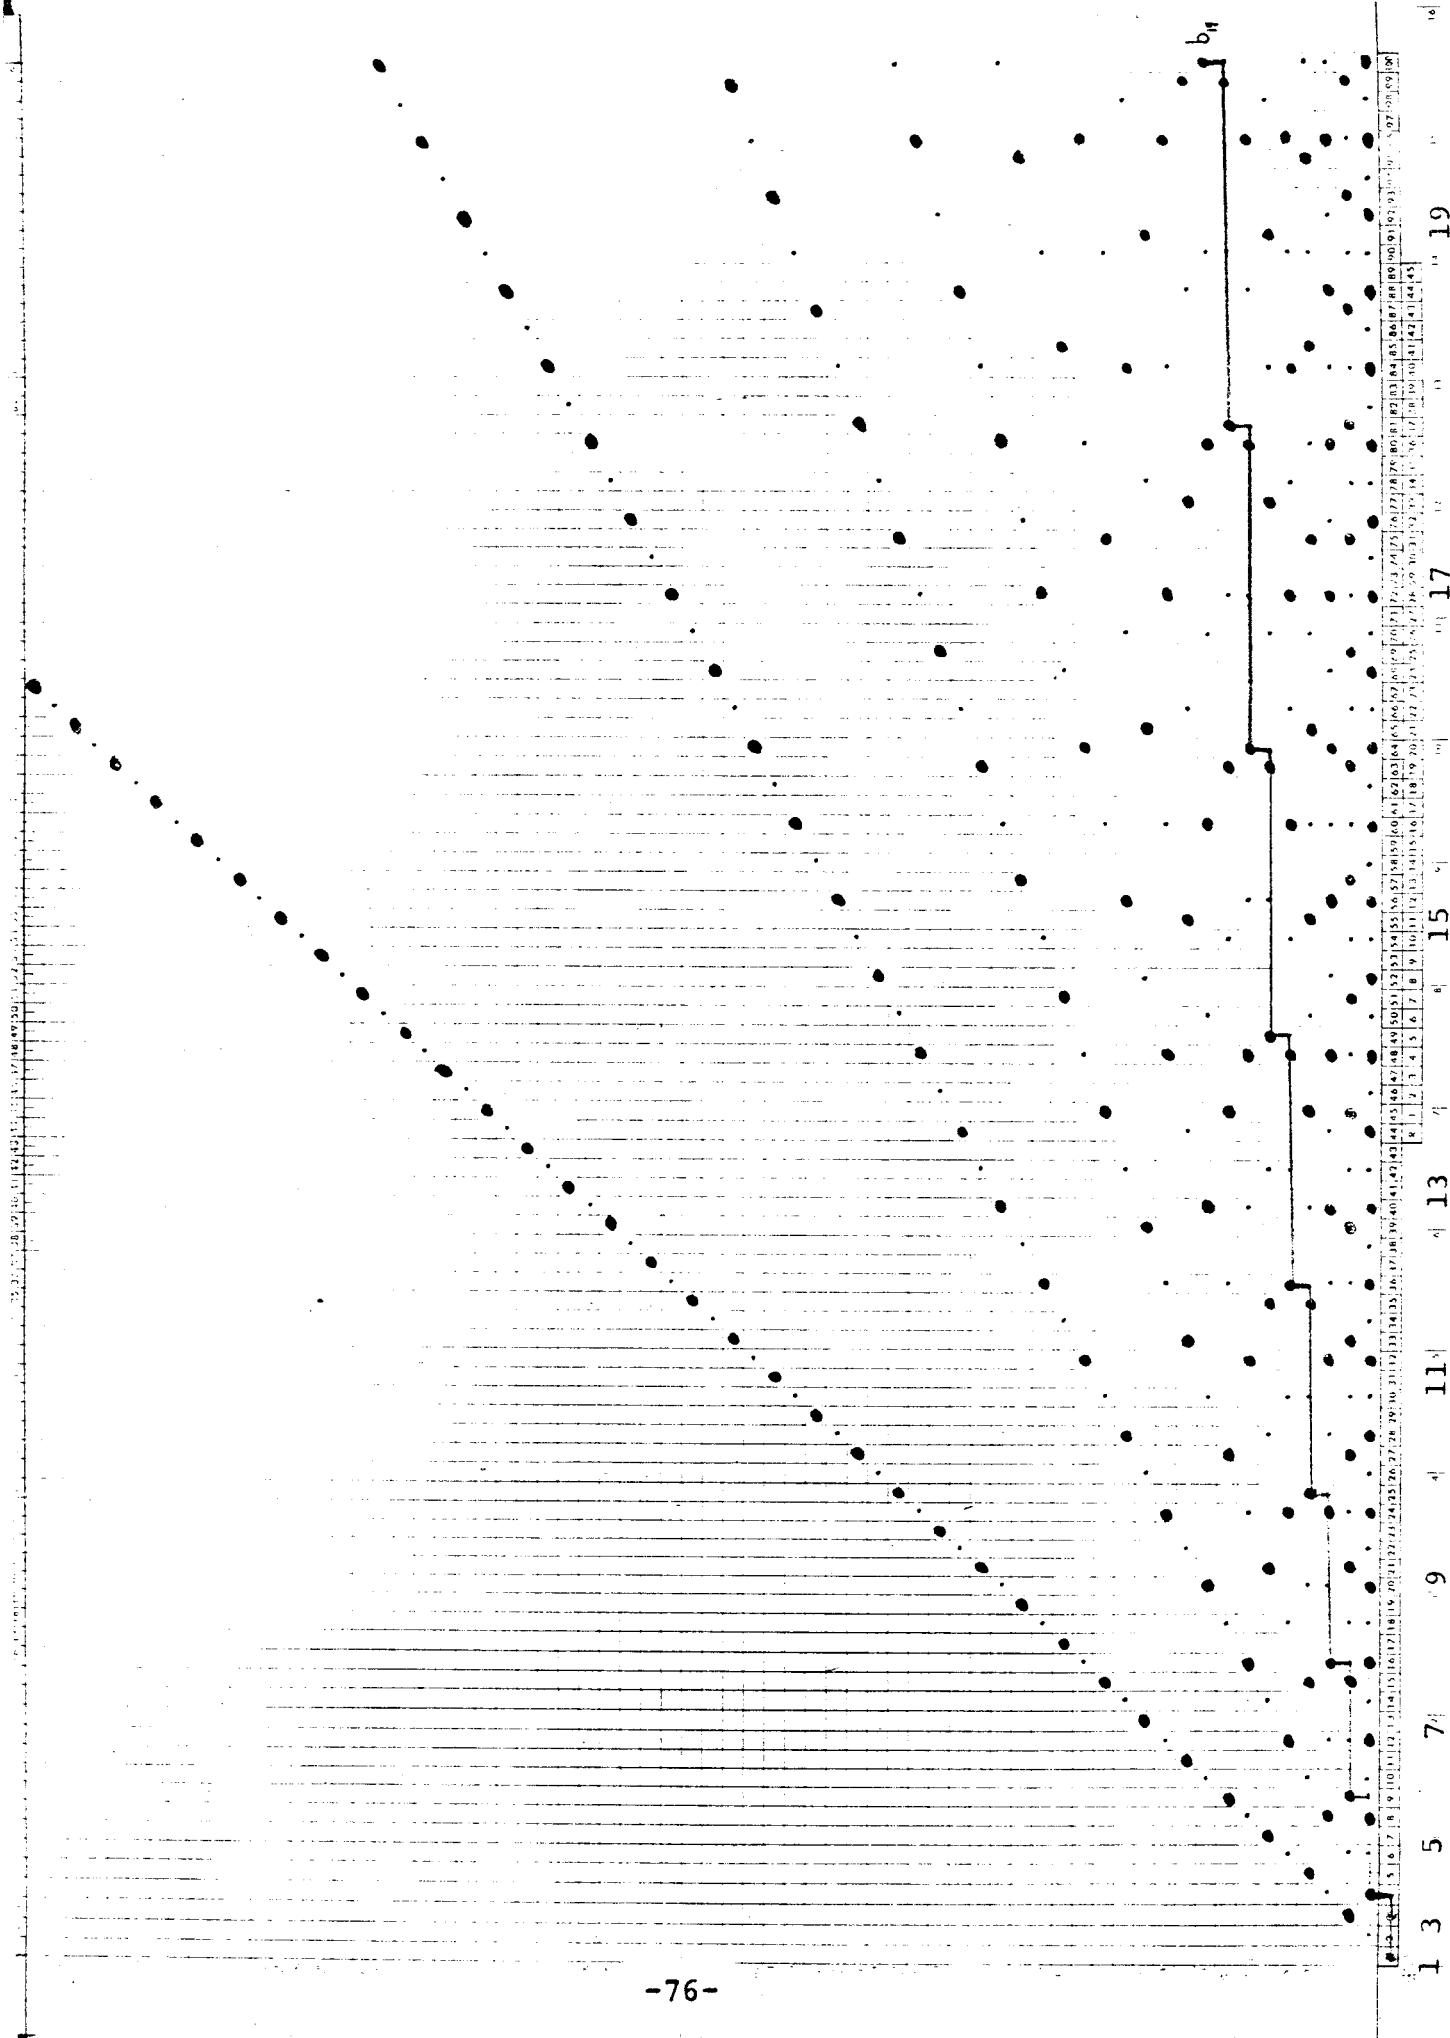

Figure 74.

The spacing of the new void adjacent curves varies somewhat from that of the odd-depositing multiplication table curves. The void curve vertexes are spaced 2, 6, 10, 14, etc., twice the spacing of the table curves (See figure 75.).

As the multiplication curve vertexes are displaced to the right one for each member (the y-value of the vertex gets one higher for each curve), the new right void adjacent curve vertexes are displaced two to the right with each curve (See figure 76.).

It turns out that this right displacement has no bearing on which vertical columns of either graph are empty when they are viewed as explained earlier for the multiplication table and with the void at the right for the new "design". These curves are of the form  $x^2 - y^2$  where  $x^2$  is the vertex and  $y$  is the dot occurrence left of the vertex ( $y^2$  is the distance left of the vertex of the  $y$ th dot) for the multiplication table family. For the new void adjacent families the form is simply  $x - y^2$  where  $x$  is the vertex and  $y^2$  is the distance of a dot to the left of the vertex.

## 15. FORMAT AND SPACING --> PRIME KIN?

Perhaps by varying the two parameters governing empty vertical column location (family member form and spacing between successive curve vertexes), various sequences of empty columns, numbered by sequences akin to that of the primes, will be generated.

Perhaps there are more patterns to be found. Who knows what we may find out there in the unexplored approaches to such knowledge? Please be my guest.

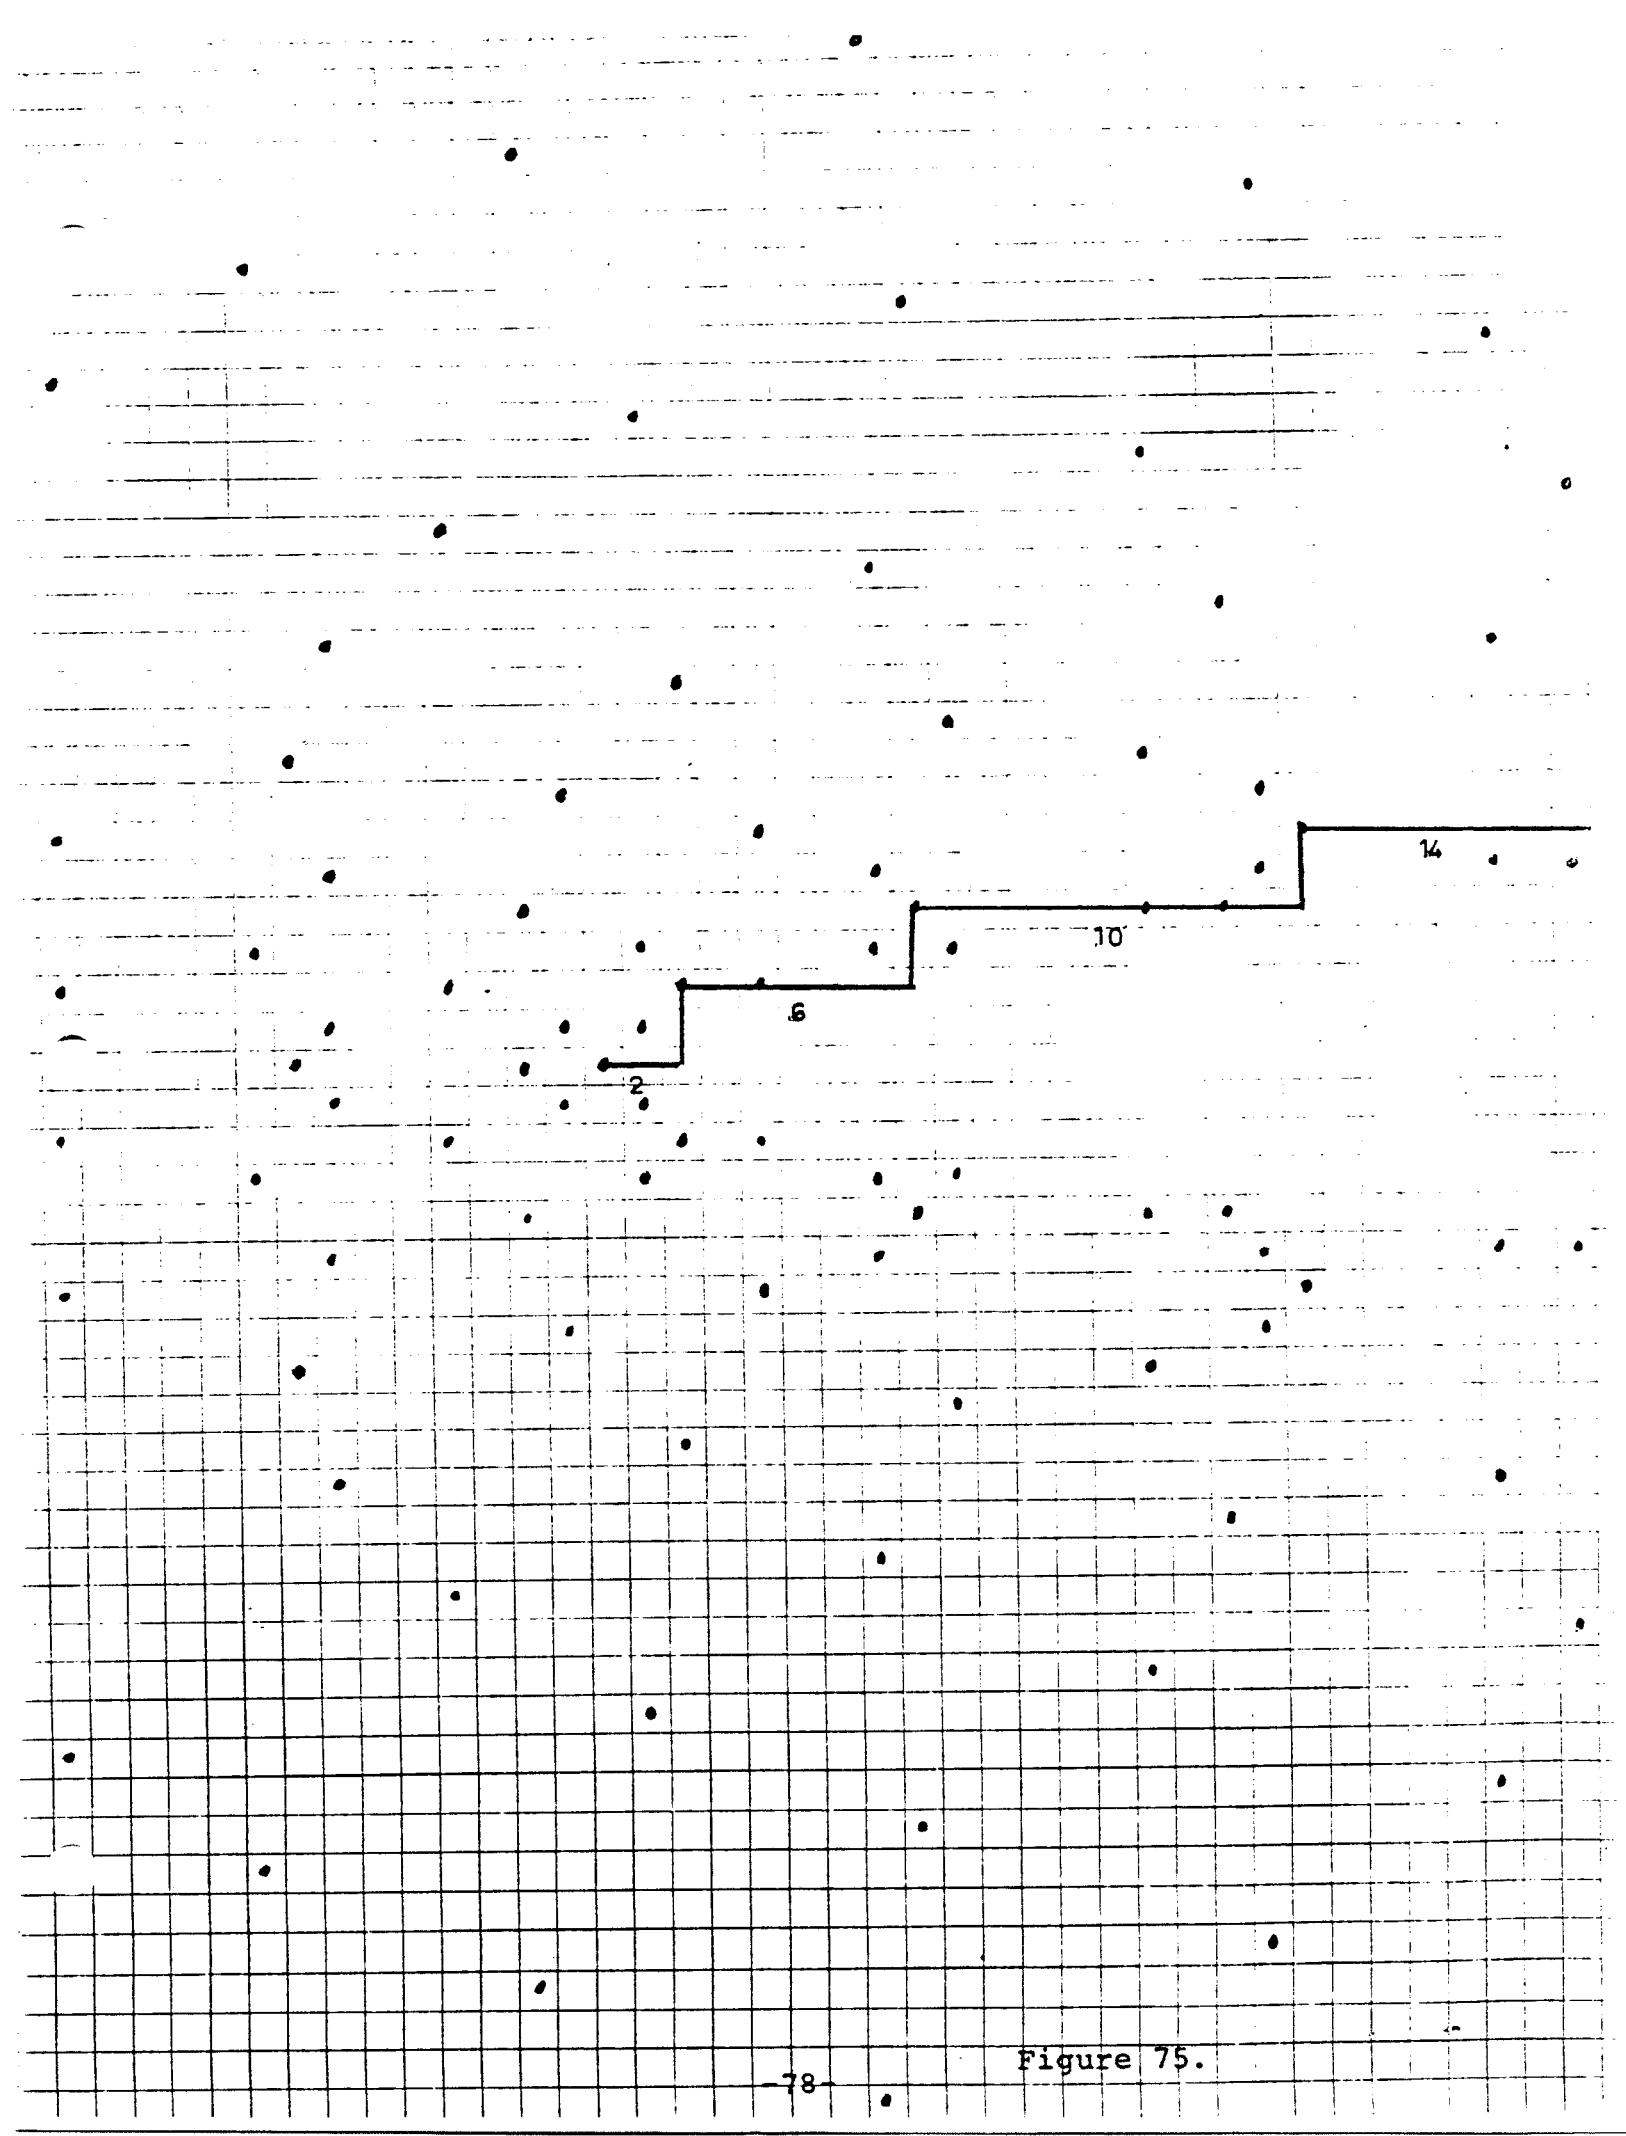

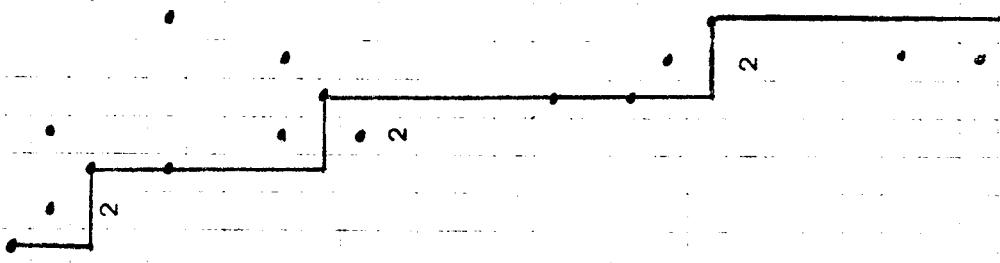

Figure 75.

Figure 76.

## APPENDIX A

### TELLING WHAT NUMBER A DOT IS

How to determine what number is represented by a dot on the triangular array:

Given the triangular array with  $n$  spots on line  $n$  like the following:

1		line 1	
2	3	line 2	
4	5	6	line 3
etc.			

Figure 77.

the coordinates of a spot may be specified as:

Line-number, Spot on the line

or

Dot(x) = Line(y), Spot(z)

When a dot's line-number is determined and its spot number on the line has been counted:

$$\text{Dot}(x) = \frac{L(L-1)}{2} + S \quad (1)$$

where  $L$  = line-number and  $S$  = spot number on the line.

For example, the dot in spot one of line 5 is:

$$\frac{5(5 - 1)}{2} + 1 = 11$$

## APPENDIX B

### TELLING WHAT SPOT A NUMBER IS

How to tell what line and which spot on it a number is represented at:

Coordinates of  $x = L, S =$

$$L = \left\lceil \frac{\sqrt{8x+1} - 1}{2} \right\rceil \quad (2a)$$

$$S = x - \left\lfloor \frac{\sqrt{8x-7} - 1}{2} \right\rfloor^2 + \left\lceil \frac{\sqrt{8x-7} - 1}{2} \right\rceil \quad (2b)$$

where  $\left\lceil \quad \right\rceil$  means "rounded up" and  $\left\lfloor \quad \right\rfloor$  means "rounded down".

For example, to tell which line and spot 11 is located at:

$$\begin{aligned} L &= \left\lceil \frac{\sqrt{8 \times 11 + 1} - 1}{2} \right\rceil = \left\lceil \frac{\sqrt{89} - 1}{2} \right\rceil = \left\lceil \frac{9+ - 1}{2} \right\rceil \\ &= \left\lceil \frac{8+}{2} \right\rceil = \left\lceil 4+ \right\rceil = 5 \end{aligned}$$

$$S = 11 - \frac{\left| \sqrt{8 \times 11 - 7} - 1 \right|^2 + \left| \sqrt{8 \times 11 - 7} - 1 \right|^2}{2}$$

$$= 11 - \frac{\left| \sqrt{81} - 1 \right|^2 + \left| \sqrt{81} - 1 \right|^2}{2}$$

$$= 11 - \frac{\left| 9 - 1 \right|^2 + \left| 9 - 1 \right|^2}{2}$$

$$= 11 - \frac{\left| \frac{8}{2} \right|^2 + \left| \frac{8}{2} \right|^2}{2}$$

$$= 11 - \frac{4^2 + 4^2}{2}$$

$$= 11 - \frac{20}{2}$$

$$= 11 - 10 = 1$$

So L, S = 5, 1.

## APPENDIX C

### THE DERIVATION OF THE FORMULAS FOR PREDICTING THE CONSTANT HORIZONTAL DISTANCE BETWEEN SUCCESSIVE MEMBER DOTS OF A CURVE IN EACH CURVE FAMILY IN "THE DESIGN"

By inspection of a single page graph of "the design" which has a grid of appropriate lines horizontally and vertically, the first few curve family horizontal constants may be ascertained. By appropriate lines I mean the same with respect to the dots of "the design" as were the grid lines of the graph on which the dots were originally plotted.

The central downward curving curve family contains identical member curves whose constant horizontal change in distance between successive member dots is one unit.

The left and right downward curving curve families both have members whose constant horizontal distance change is two units.

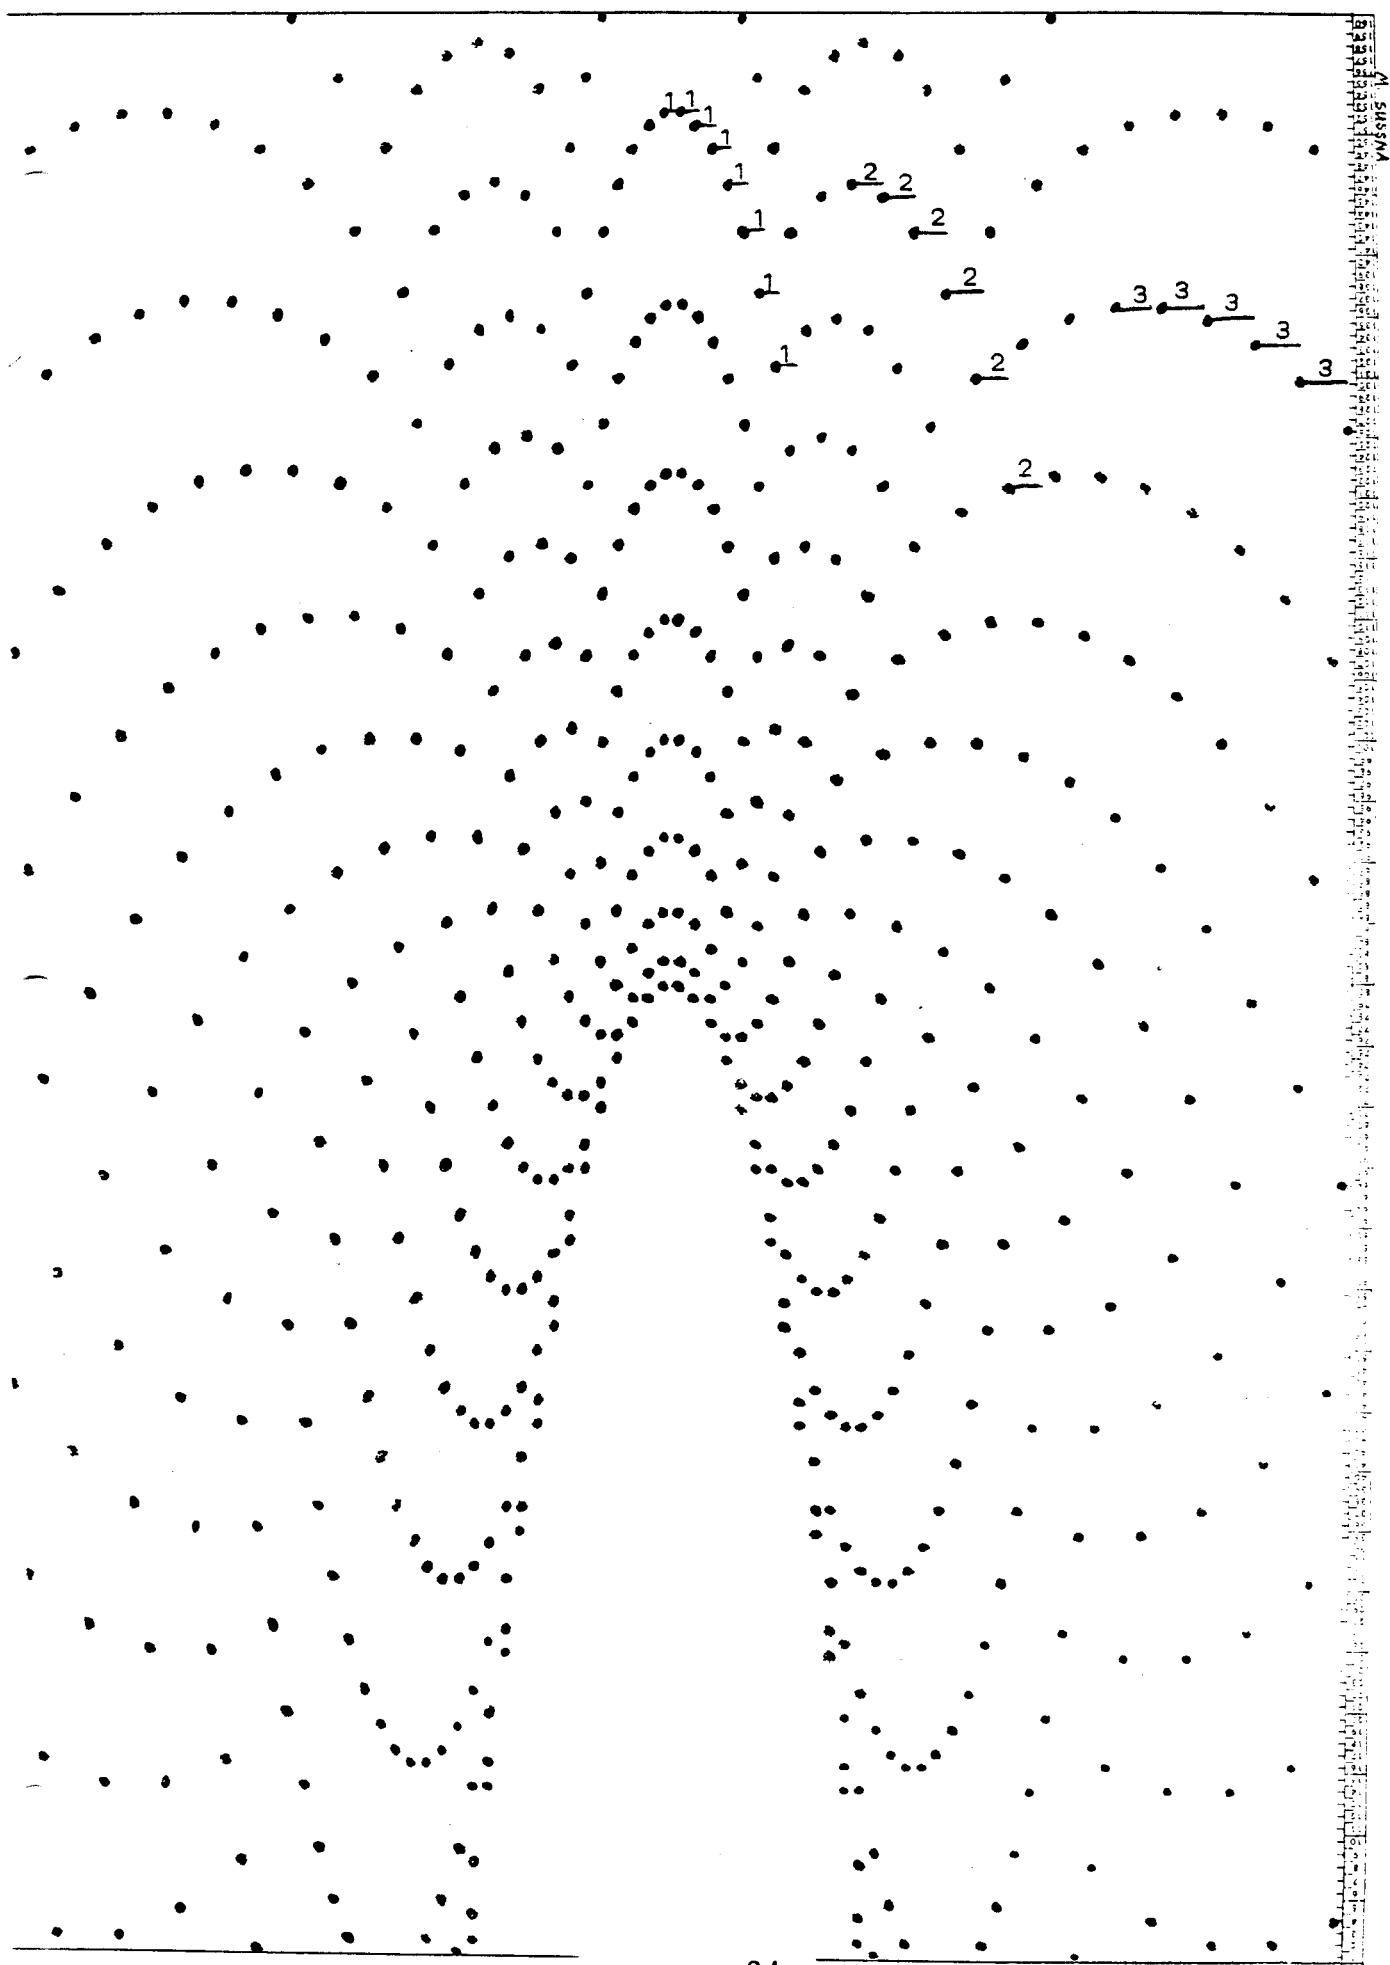

The far left and right downward curving curve families have a horizontal constant of three units. A seemingly simple progression, eh? (See figure 78.)

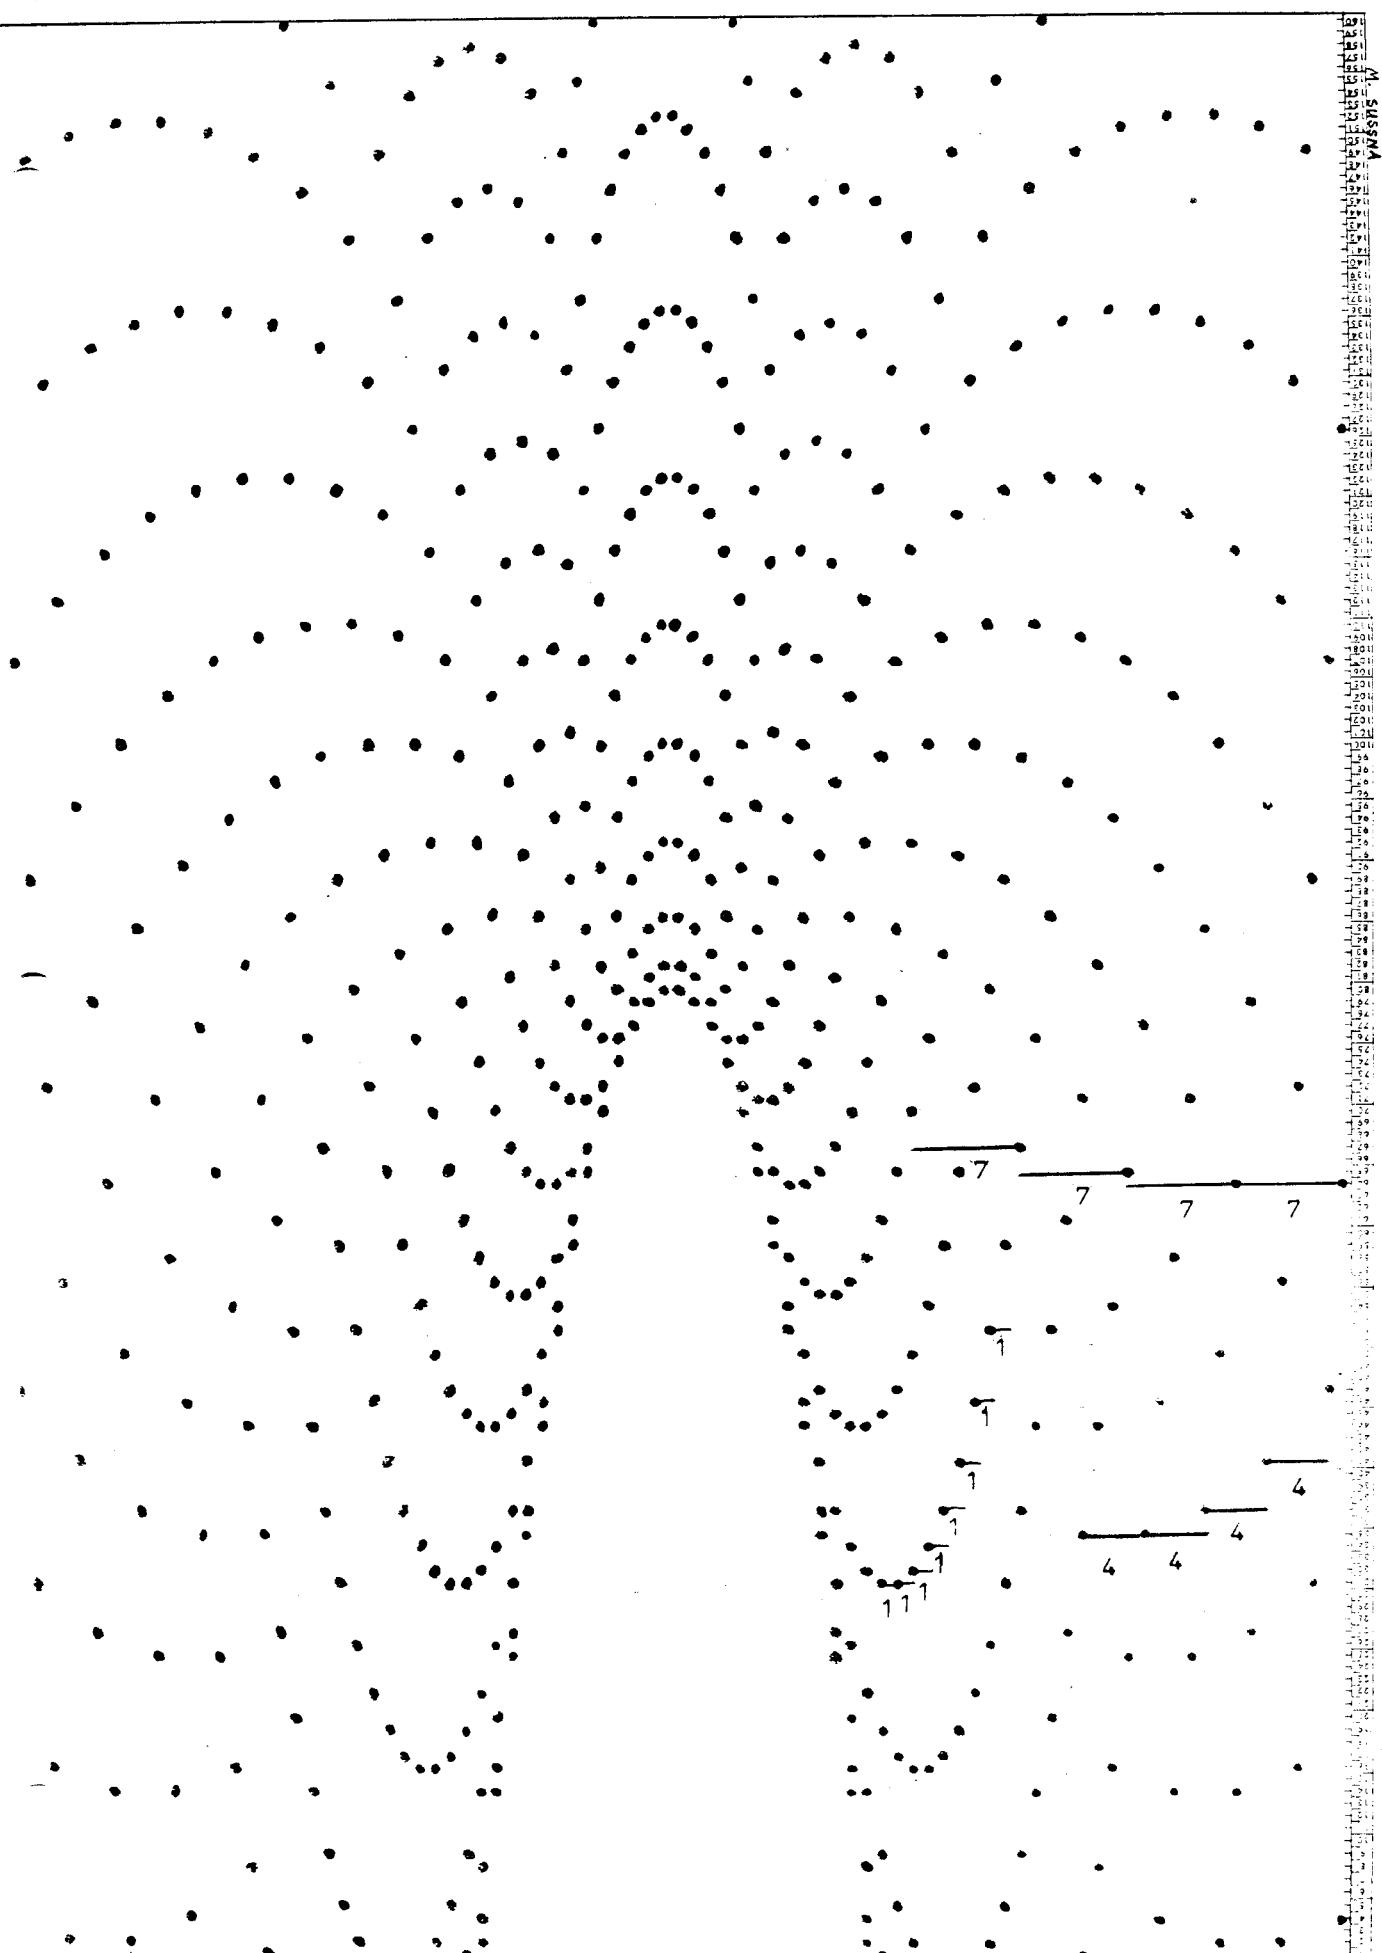

What about the upward curving families? The left and right void adjacent families have a horizontal constant of one unit, while the far left and right void adjacent curve families have a horizontal constant of four units. By properly sighting along the dots, the third set of left and right void adjacent families may be perceived. This third upward curving family pair has a horizontal constant of seven. (See figure 79.) 1, 4, 7 -- another seemingly simple progression, right?

Well, the fourth set of downward curving curve families has a horizontal constant of 10.

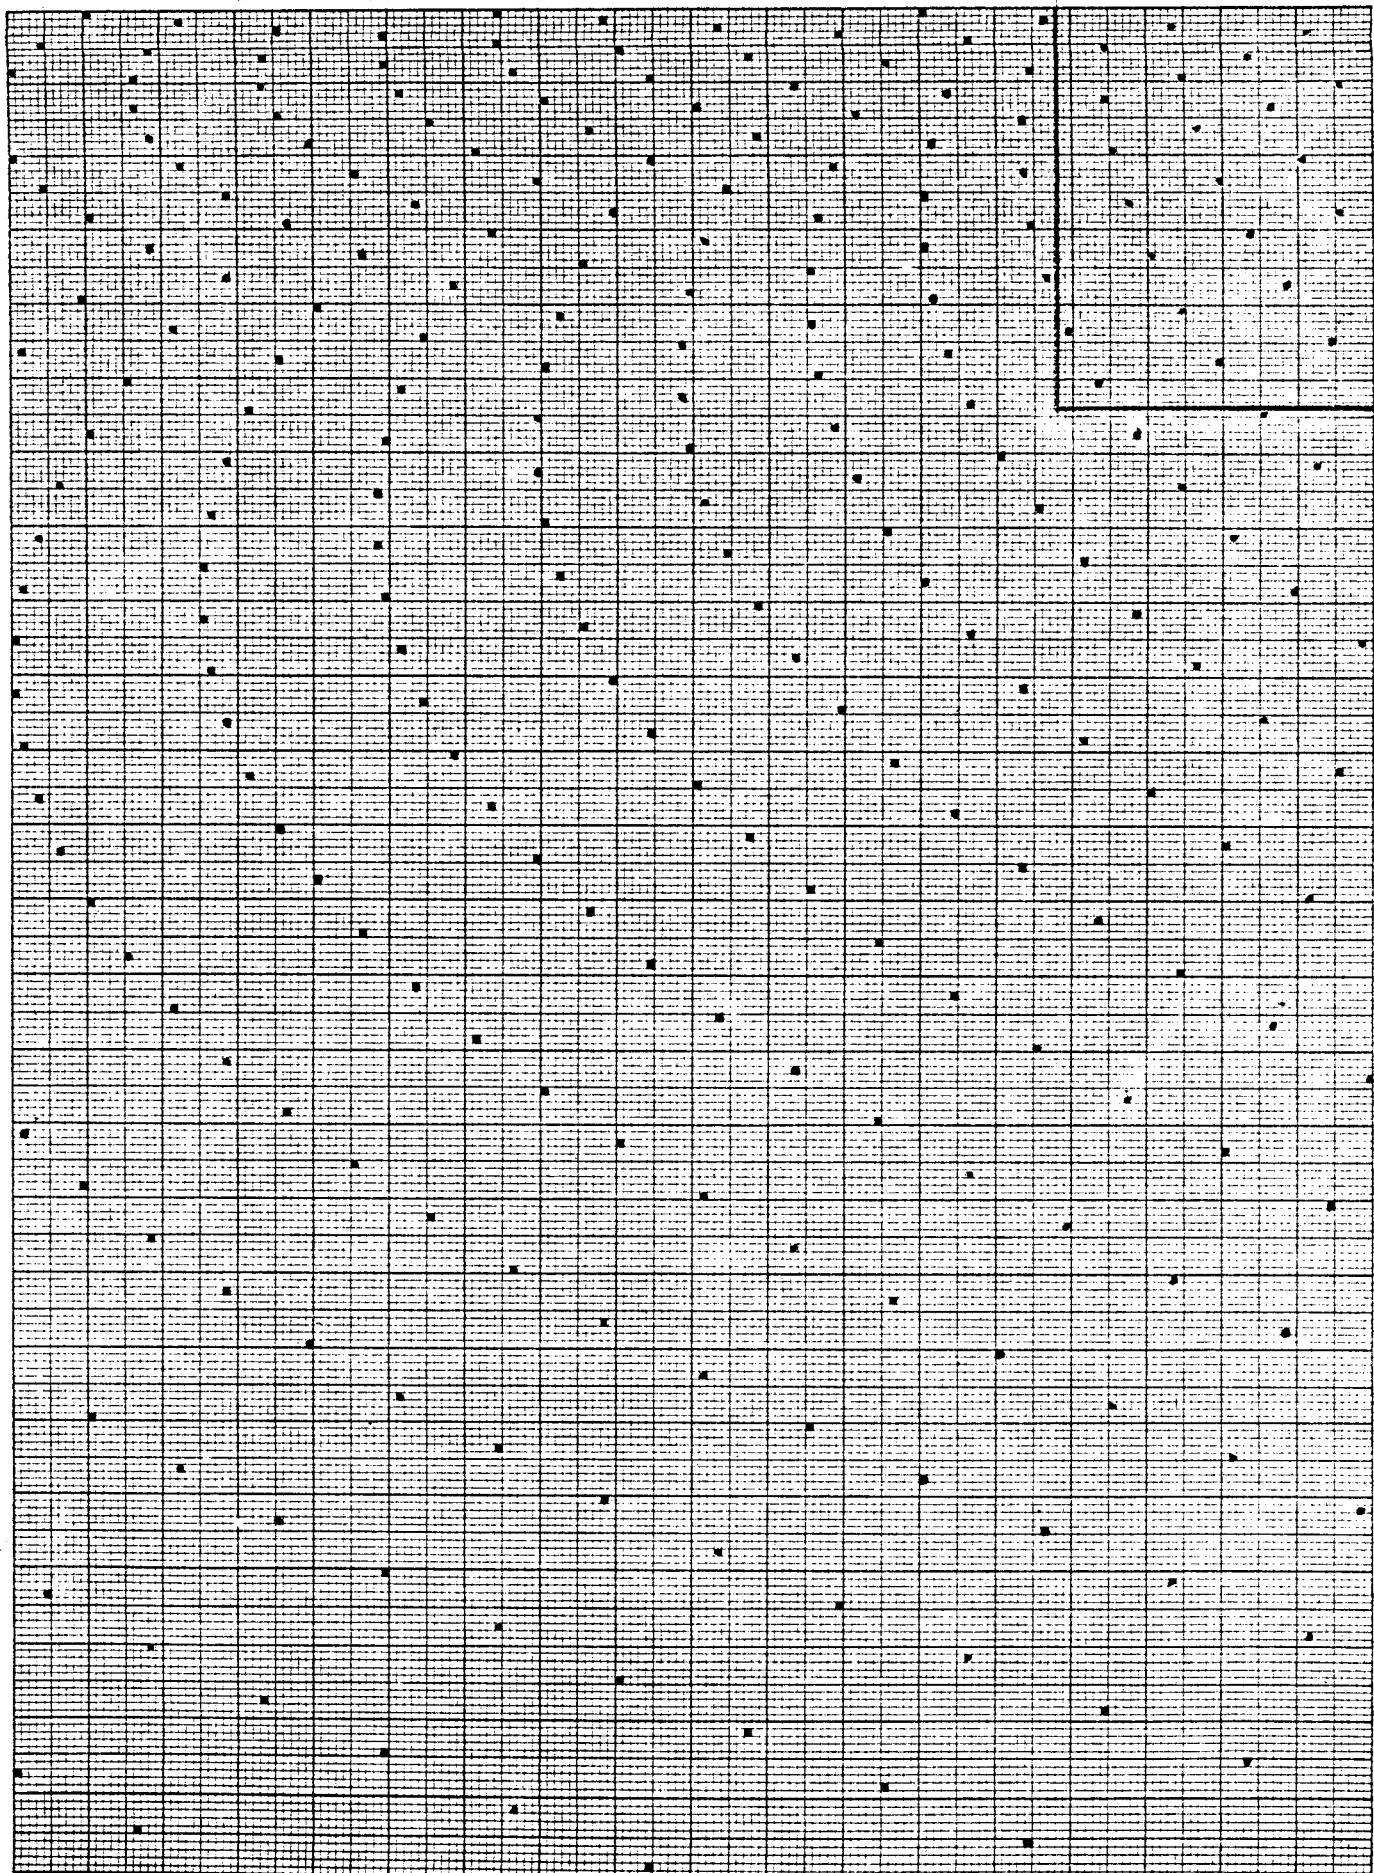

By taking a remote section of "the design", a section to the right of the right edge of the paper when the void is at the bottom (See figure 80.), graphing it onto a very finely lined piece of graph paper (See figure 81.), and extending the patterns in a continuation of "the design", I was able to determine that the fourth set of upward curving families has a horizontal constant of 24. (See figure 82.) (To see how figure 80's points relate to "the design", the upper left corner of figure 80 appears as the rectangle on the lower right in figure 83. The top of figure 83 appears as the larger rectangle in figure 84. That's the very top of figure 80 appearing as the smaller rectangle in figure 84.)

By similar means, I verified that the fifth members of

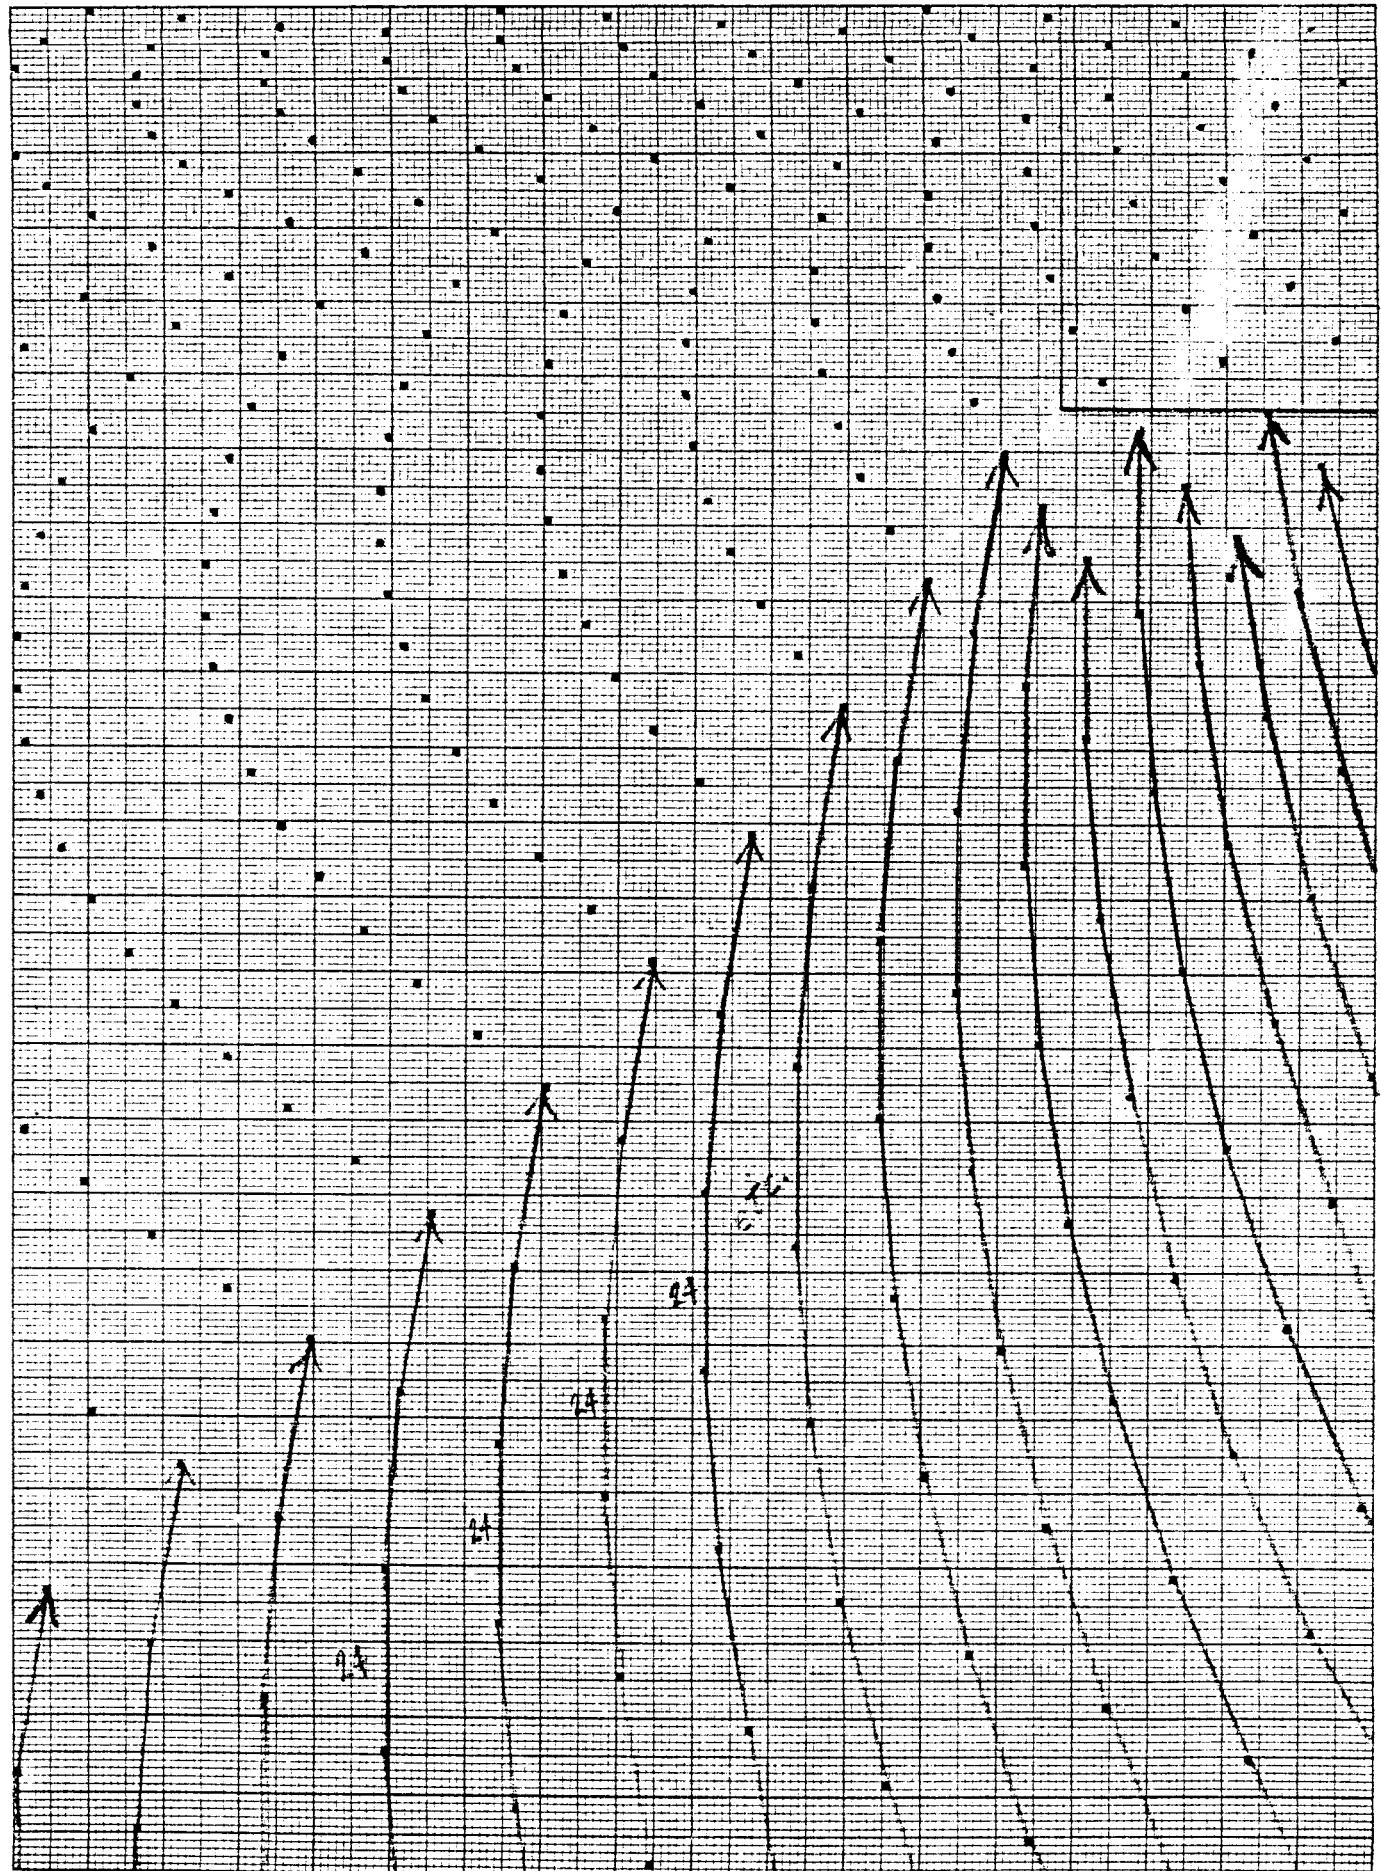

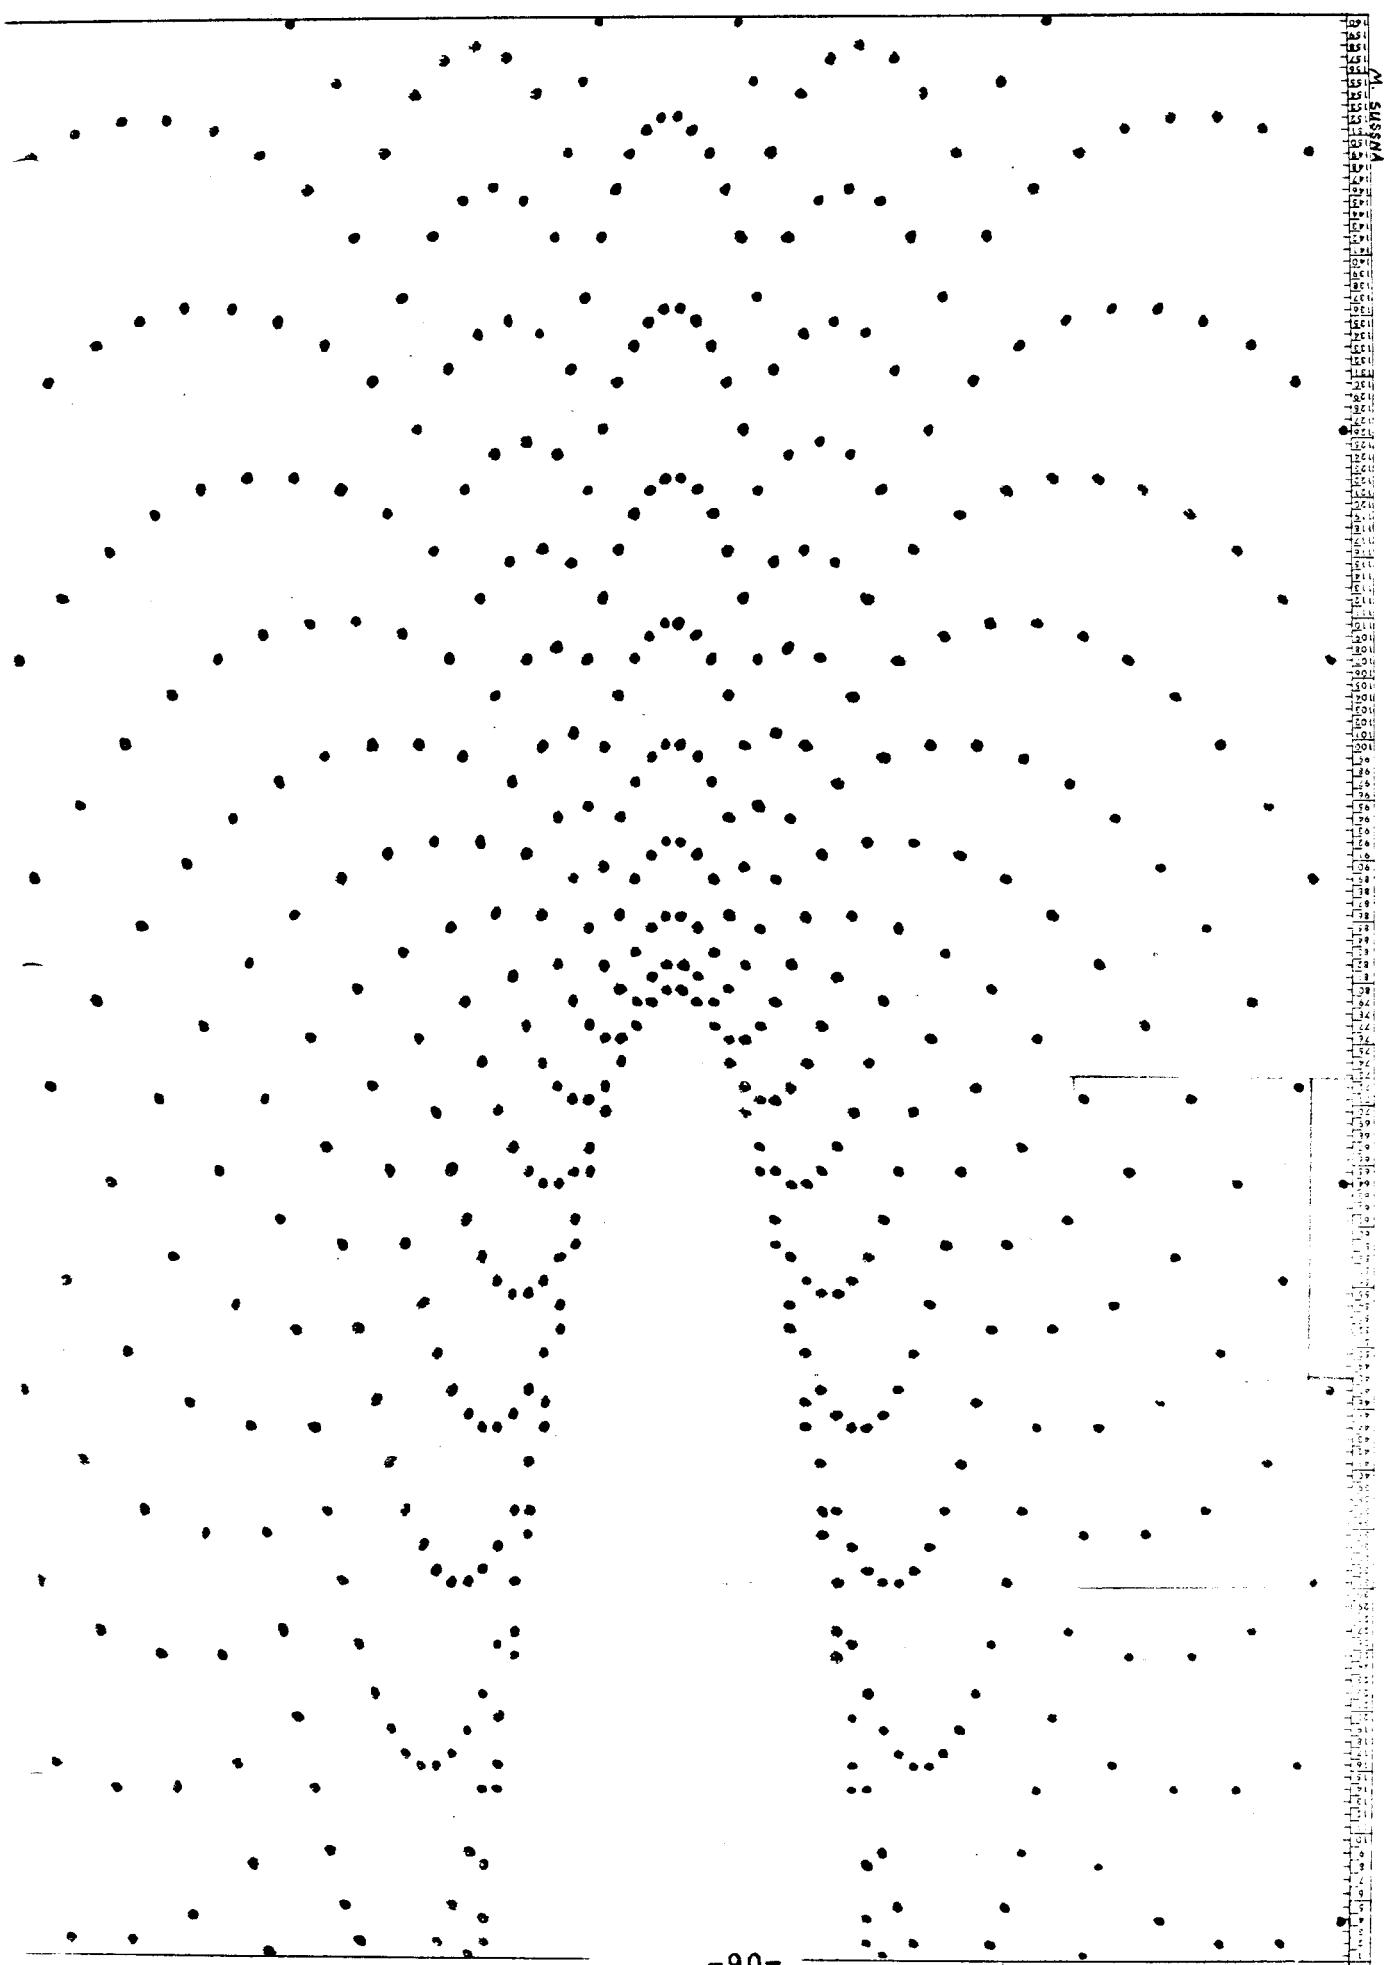

Figure 84.

the two lists are 17 and 41, for downward and upward curving curve families, respectively. (See figures 85 and 86 respectively.)

The list of constants was taking the following shape:

Downward curving	Upward curving
1	1
2	4
3	7
10	24
17	41

Figure 87.

With this much data it became possible to begin to see the pattern in these constants:

D	U
-	-
1	1
1	3
2	4
1	3
3	7
7	17
10	24
7	17
17	41

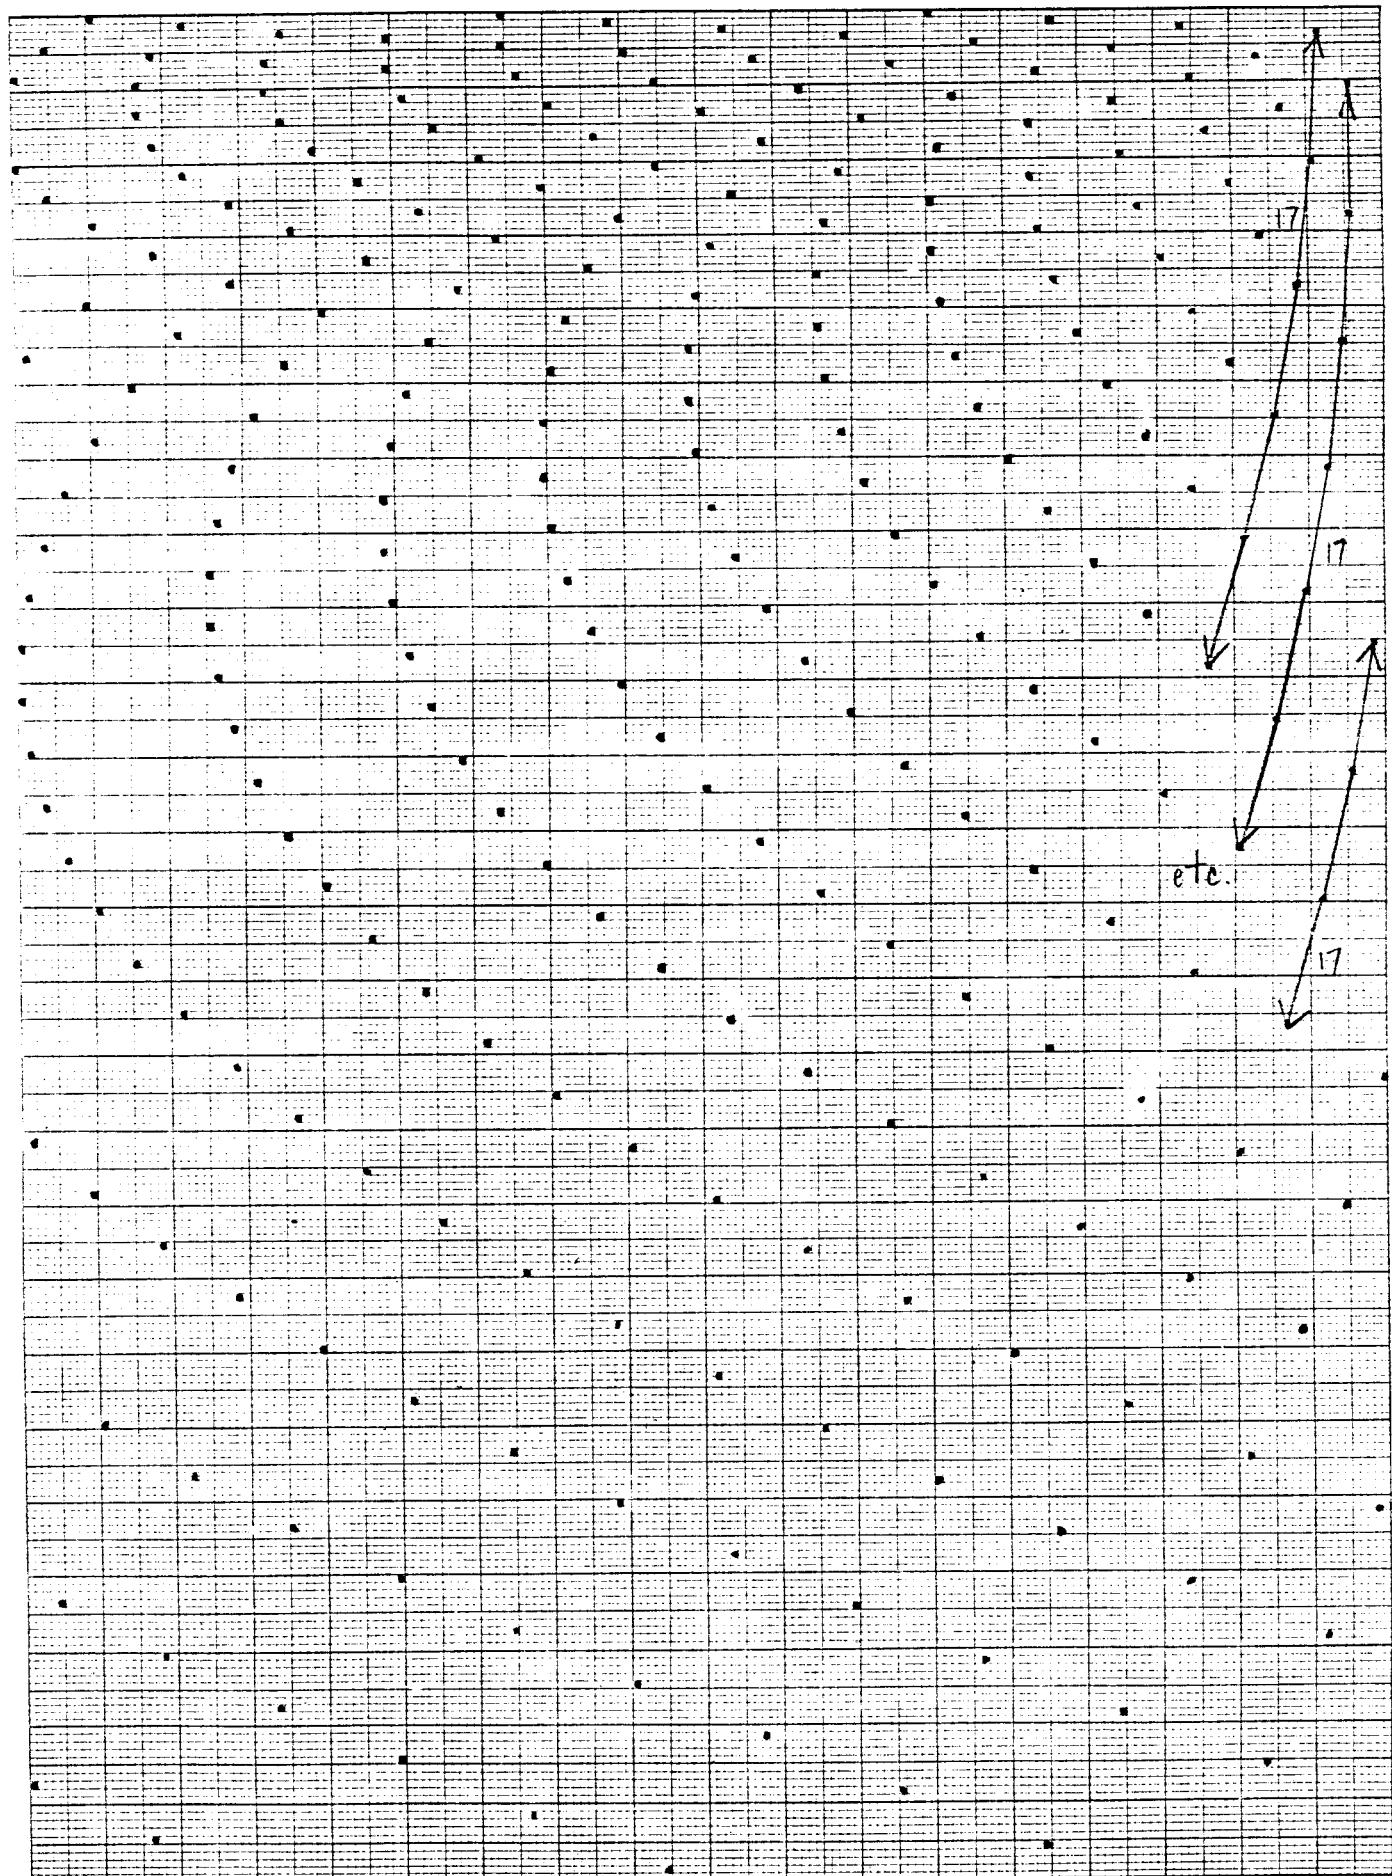

Figure 88.

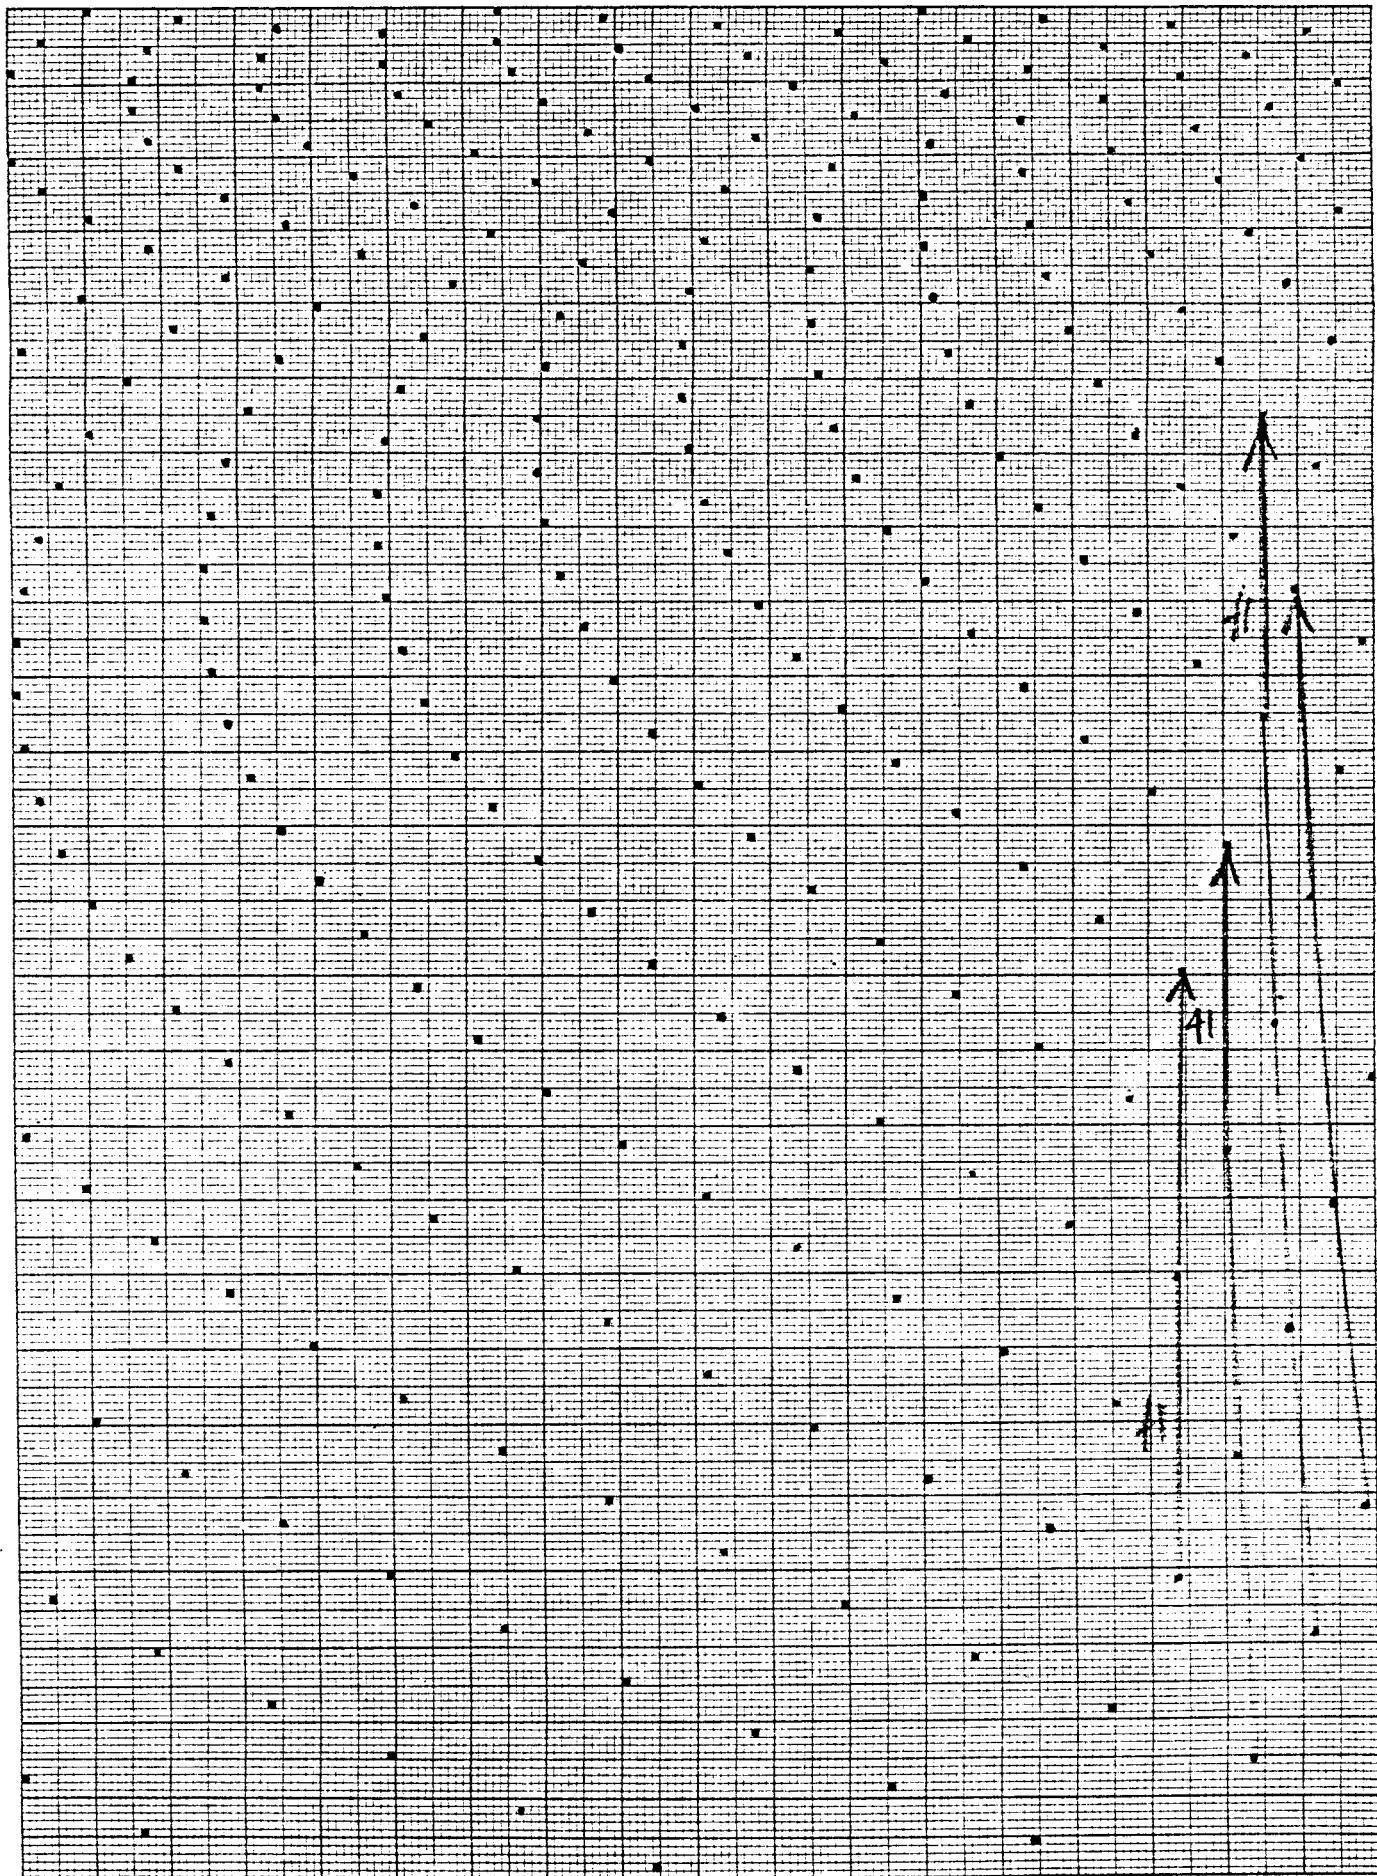

The differences come in pairs - two ones, two threes, two sevens, and two 17's. If that progression of differences (1, 3, 7, 17) could be "cracked", then perhaps the once simple seeming constant lists could still be deciphered.

By rewriting the pair of lists offset by one, a neat effect occurs:

D	U	D+U
-	-	---
1	0	1
2	1	3
3	4	7
10	7	17
17	24	41
	41	

Figure 89.

Our difference progression 1, 3, 7, 17 is the sum across the pair of lists for the first four entries of the pair:

$$D(n) + U(n-1) = \text{Diff}(n) \quad (3)$$

The five sums on the right all appear as individual members of the list pair in this way:

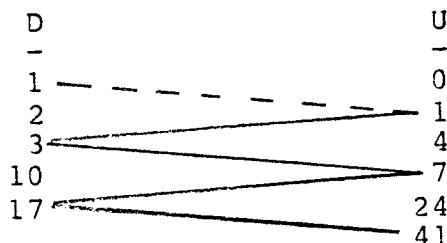

Figure 90.

Should the two 1's connected by the dotted line be connected? For the first 1 in the D list to be admitted to the sequence 1, 3, 7, 17 it should be a difference pair in the U list in the following way:

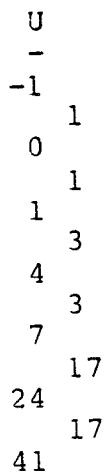

Figure 91.

By the same token, 41 should be the next difference

pair in the D list thus:

D	
-	
1	1
2	1
3	7
10	7
17	41
58	41
99	

Figure 92.

Is there any way to check the truth of these extrapolations? Yes. There should be detectable left and right downward curving curve families with a constant horizontal change in distance between successive dots in a member curve equal to these extrapolated values. There are. First, in the U list, curves with a 0 constant are "in" the void, and curves with a constant of -1 correspond to the left void adjacent curves, if we started on the right of the void. Downward curving curves with a horizontal constant of 58 can be seen in figure 93.

Now, to get a feel for what type of formula the U and D lists might have, I recognized the resemblance between the difference progression  $1, 1, 3, 7, 17, 41, \dots$  and the Fibonacci numbers  $1, 1, 2, 3, 5, 8, 13, \dots$  and so on. While each Fibonacci number is the sum of the two preceding Fibonacci numbers, the difference numbers are the sum of the immediately preceding number doubled and the number preceding that:

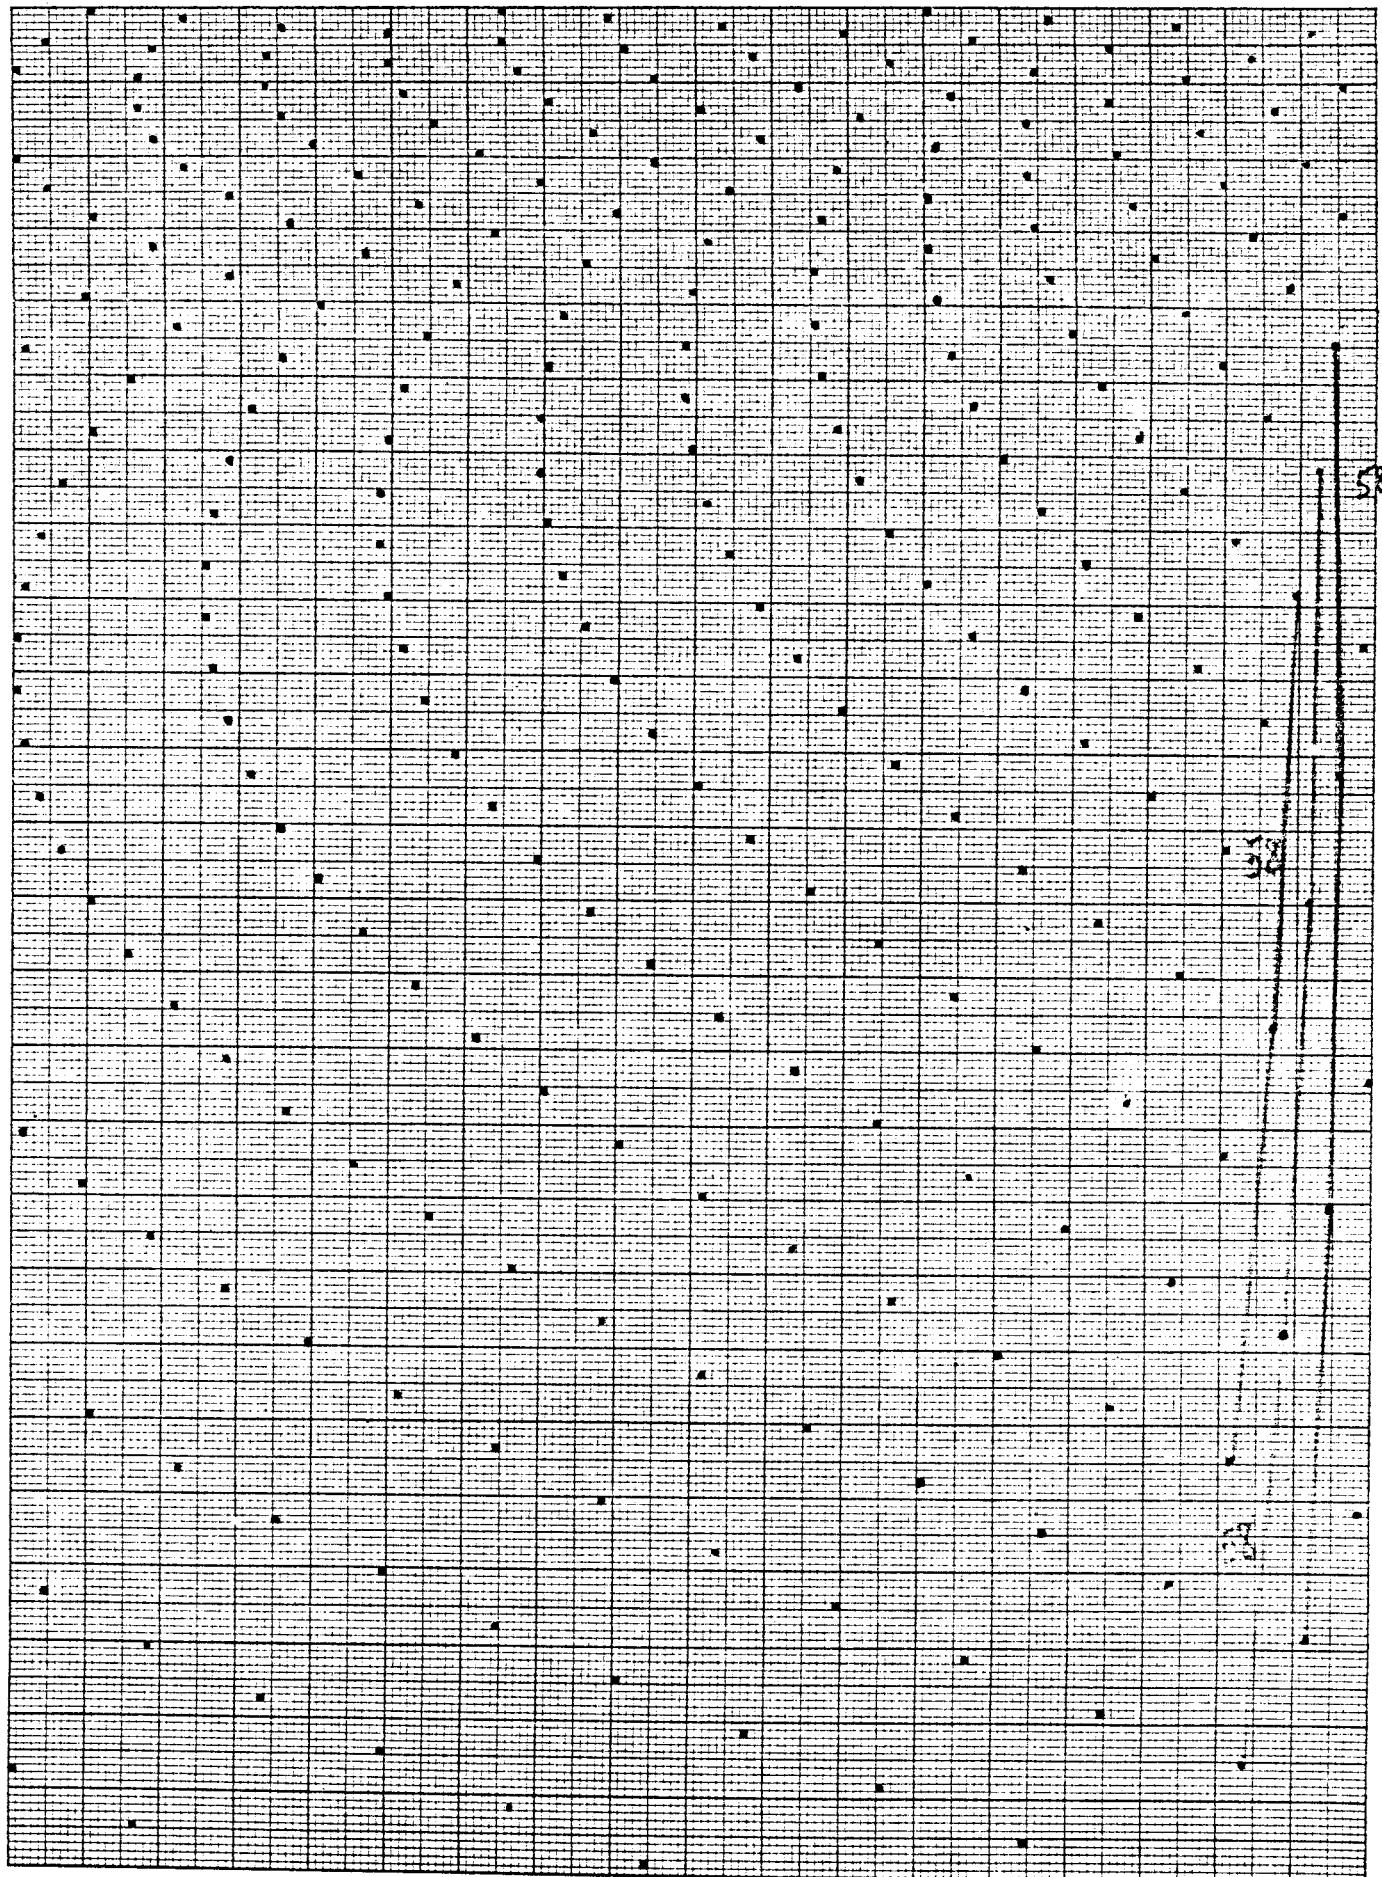

$$\text{Fibo}(n) = \text{Fibo}(n-1) + \text{Fibo}(n-2) \quad (4)$$

$$\text{Diff}(n) = 2 \times \text{Diff}(n-1) + \text{Diff}(n-2) \quad (5)$$

Perhaps the formula for the difference numbers would resemble the formula for the Fibonacci numbers:

$$\text{Fibo}(n) = \frac{1}{\sqrt{5}} \left[ \left( \frac{1 + \sqrt{5}}{2} \right)^n - \left( \frac{1 - \sqrt{5}}{2} \right)^n \right] \quad (6)$$

The key to such a formula is the term being raised to the nth power.

For example  $(1 + \sqrt{5})^n$  goes through interesting gyrations from power to power. The resulting coefficients contain the seeds of the Fibonacci numbers:

$$(1 + \sqrt{5})^0 = 1 \quad (7)$$

$$(1 + \sqrt{5})^1 = 1 + \sqrt{5} \quad (8)$$

$$(1 + \sqrt{5})^2 = 6 + 2\sqrt{5} \quad (9)$$

$$(1 + \sqrt{5})^3 = 16 + 8\sqrt{5} \quad (10)$$

$$(1 + \sqrt{5})^4 = 56 + 24\sqrt{5} \quad (11)$$

$$(1 + \sqrt{5})^5 = 176 + 80\sqrt{5} \quad (12)$$

and so on.

The multiples of  $\sqrt{5}$  in each result form a pattern:

1  
2  
8  
24  
80

Figure 94.

When these numbers are doubled, we get:

2  
4  
16  
48  
160

Figure 95.

When these numbers are divided by successive powers of two we get the Fibonacci numbers:

2 / 2 = 1  
4 / 4 = 1  
16 / 8 = 2  
48 / 16 = 3  
160 / 32 = 5

Figure 96.

The rest of the items in the formula for the Fibonacci numbers besides  $(1 + \sqrt{5})^n$  are merely what is needed to isolate those key multiples mentioned above and scale them down properly (double them and divide the result by the appropriate power of two).

It was with this in mind that I set out to conquer the difference progression of numbers.

I first tried variations on  $(1 + \sqrt{5})^n$  like  $(2 + \sqrt{5})^n$  and  $(1 + 2\sqrt{5})^n$  but the sequences of coefficients grew too rapidly.

Next I tried  $(1 + \sqrt{3})^n$ . This was better but still not right.

With my next try, I struck it rich:

$$(1 + \sqrt{2})^0 = 1 \quad (13)$$

$$(1 + \sqrt{2})^1 = 1 + \sqrt{2} \quad (14)$$

$$(1 + \sqrt{2})^2 = 3 + 2\sqrt{2} \quad (15)$$

$$(1 + \sqrt{2})^3 = 7 + 5\sqrt{2} \quad (16)$$

$$(1 + \sqrt{2})^4 = 17 + 12\sqrt{2} \quad (17)$$

$$(1 + \sqrt{2})^5 = 41 + 29\sqrt{2} \quad (18)$$

and so on.

This time we wish to isolate the coefficients of the non-square-root part of the result when the key term is raised to the nth power. This is done easily enough:

$$1 = \frac{(1 + \sqrt{2}) + (1 - \sqrt{2})}{2} \quad (19)$$

$$3 = \frac{(3 + 2\sqrt{2}) + (3 - 2\sqrt{2})}{2} \quad (20)$$

etc.

It so happens that  $(1 - \sqrt{2})^n$  looks exactly like

$(1 + \sqrt{2})^n$  when multiplied out, except for the sign between the non-  $\sqrt{2}$  part and the  $\sqrt{2}$  part of the result.

For example,

$$(1 + \sqrt{2})^4 = 17 + 12\sqrt{2}$$

while

$$(1 - \sqrt{2})^4 = 17 - 12\sqrt{2}$$

and so on.

So, difference number n equals

$$\frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2}. \quad (21)$$

Now, how can the D and U lists be expressed based on the preceding find? We start with the following table:

n	D	U	Diff
-	-	-	----
1	1	1	1
2	2	4	3
3	3	7	7
4	10	24	17
5	17	41	41

Figure 97.

It would seem that the odd D's and U's correspond to the difference numbers:

$$\begin{array}{ll} D(1) = \text{Diff}(0) & U(1) = \text{Diff}(1) \\ D(3) = \text{Diff}(2) & U(3) = \text{Diff}(3) \\ D(5) = \text{Diff}(4) & U(5) = \text{Diff}(5) \end{array}$$

Figure 98.

So  $D(n) = \text{Diff}(n-1)$  when n is odd, and  $U(n) = \text{Diff}(n)$  when n is odd.

What about when n is even? We'll need our earlier finding that  $D(n) + U(n-1) = \text{Diff}(n)$ .

By rearranging terms we get:

$$D(n) = \text{Diff}(n) - U(n-1). \quad (22)$$

Now if  $n$  is even, an even  $D$ ,  $D(n)$ , equals  $\text{Diff}(n)$  minus  $U(n-1)$ , an odd  $U$ . We know  $U(n) = \text{Diff}(n)$  for odd  $n$ 's, so

$$U(n-1) = \text{Diff}(n-1). \quad (23)$$

We now have  $D(n) = \text{Diff}(n) - \text{Diff}(n-1)$  when  $n$  is even.

All that's left to express in terms of the difference progression is  $U(n)$  when  $n$  is even.

We again call on equation 3:

$$D(n) + U(n-1) = \text{Diff}(n)$$

This time we rearrange the terms this way:

$$U(n-1) = \text{Diff}(n) - D(n). \quad (24)$$

We want an even  $U$ , so  $n-1$  is even. That means that  $n$  is odd.

$D(n) = \text{Diff}(n-1)$  for odd  $n$ , so, for even  $n$ :

$$U(n-1) = \text{Diff}(n) - \text{Diff}(n-1) \quad (25)$$

$$\text{or} \\ U(n) = \text{Diff}(n+1) - \text{Diff}(n). \quad (26)$$

For example:

$$U(4) = \text{Diff}(5) - \text{Diff}(4)$$

or

$$24 = 41 - 17.$$

To summarize:

	$D(n)$	$U(n)$
ODD	Diff(n-1)	Diff(n)
EVEN	Diff(n) - Diff(n-1)	Diff(n+1) - Diff(n)

Figure 99.

or

	$D(n)$	$U(n)$
ODD	$\frac{(1 + \sqrt{2})^{n-1} + (1 - \sqrt{2})^{n-1}}{2}$	$\frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2}$
EVEN	$\frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2}$	$\frac{(1 + \sqrt{2})^{n+1} + (1 - \sqrt{2})^{n+1}}{2}$
	$\frac{(1 + \sqrt{2})^{n-1} + (1 - \sqrt{2})^{n-1}}{2}$	$\frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2}$

Figure 100.

The complicated expressions for  $D(n)$  and  $U(n)$  for even  $n$ 's may be simplified in the following way:

$$D(n) = \frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2} - \frac{(1 + \sqrt{2})^{n-1} + (1 - \sqrt{2})^{n-1}}{2} \quad (27)$$

$$= \frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n - (1 + \sqrt{2})^{n-1} - (1 - \sqrt{2})^{n-1}}{2}$$

$$\begin{aligned}
&= \frac{(1 + \sqrt{2})^n - (1 + \sqrt{2})^{n-1} + (1 - \sqrt{2})^n - (1 - \sqrt{2})^{n-1}}{2} \\
&= \frac{[(1 + \sqrt{2})^n - (1 + \sqrt{2})^{n-1}] + [(1 - \sqrt{2})^n - (1 - \sqrt{2})^{n-1}]}{2} \\
&= \frac{[(1 + \sqrt{2})(1 + \sqrt{2})^{n-1} - (1 + \sqrt{2})^{n-1}] + [(1 - \sqrt{2})(1 - \sqrt{2})^{n-1} - (1 - \sqrt{2})^{n-1}]}{2} \\
&= \frac{(1 + \sqrt{2})^{n-1} [(1 + \sqrt{2}) - 1] + (1 - \sqrt{2})^{n-1} [(1 - \sqrt{2}) - 1]}{2} \\
&= \frac{[(1 + \sqrt{2})^{n-1} (1 + \sqrt{2} - 1)] + [(1 - \sqrt{2})^{n-1} (1 - \sqrt{2} - 1)]}{2} \\
&= \frac{[(1 + \sqrt{2})^{n-1} (\sqrt{2})] - [(1 - \sqrt{2})^{n-1} (\sqrt{2})]}{2} \\
&= \frac{\sqrt{2}[(1 + \sqrt{2})^{n-1} - (1 - \sqrt{2})^{n-1}]}{2}
\end{aligned}$$

So,  $D(n)$  for even  $n$  =

$$\frac{(1 + \sqrt{2})^{n-1} - (1 - \sqrt{2})^{n-1}}{\sqrt{2}} \quad (28)$$

By the same procedure for  $U(n)$  for even  $n$ 's, where

$$U(n) = \frac{(1 + \sqrt{2})^{n+1} + (1 - \sqrt{2})^{n+1}}{2} - \frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2} \quad (29)$$

we arrive at

$$U(n) = \frac{(1 + \sqrt{2})^n - (1 - \sqrt{2})^n}{\sqrt{2}} \quad (30)$$

for even  $n$ .

Here is the revised summary:

	$D(n)$	$U(n)$
ODD	$\frac{(1 + \sqrt{2})^{n-1} + (1 - \sqrt{2})^{n-1}}{2}$	$\frac{(1 + \sqrt{2})^n + (1 - \sqrt{2})^n}{2}$
EVEN	$\frac{(1 + \sqrt{2})^{n-1} - (1 - \sqrt{2})^{n-1}}{\sqrt{2}}$	$\frac{(1 + \sqrt{2})^n - (1 - \sqrt{2})^n}{\sqrt{2}}$

Figure 101.

## 16. PATTERNS WITH LINE CONTINUATION

WHEN THE LINES OF PRIMES GENERATED BY THE NINE FORMULAS OF THE FAMILY OF FORMULAS REACH THE POINT WHERE THEY ARE FINALLY BROKEN, IT COULD EASILY BE ASSUMED THAT THERE IS NO MORE ORDERLINESS BEYOND THAT POINT. SUCH IS NOT THE CASE.

THERE ARE PATTERNS OF PRIMENESS AND NON-PRIMENESS FOR A LITTLE WAY BEYOND THAT BREAK FOR EACH OF THE NINE LINES.

FOR EXAMPLE, TAKE  $X^2 + X + 41$ . FOR THE FIRST 40 VALUES OF  $X$  (0 THROUGH 39)  $X^2 + X + 41$  IS PRIME. FOR 40 AND 41 IT IS NOT PRIME. FOR 42 AND 43 IT IS. FOR 45 - 48 IT IS. FOR 50 - 55 IT IS. FOR 57 - 64 IT IS. FOR 66 - 75 IT IS.

THE PATTERN THUS FORMED LOOKS LIKE THIS:

X	X'S IN A ROW PRIME?
0 - 39	40 Y
40 & 41	2 N
42 & 43	2 Y
44	1 N
45 - 48	4 Y
49	1 N
50 - 55	6 Y
56	1 N
57 - 64	8 Y
65	1 N
66 - 75	10 Y
76	1 N
77 - 84	12 Y
85	1 N
86 - 93	14 Y
94	1 N
95 - 102	16 Y
103	1 N
104 - 111	18 Y
112	1 N
113 - 120	20 Y
121	1 N

HOW DOES THIS PATTERN COMPARE WITH THOSE OF THE OTHER EIGHT LINES?

HERE ARE THE PATTERNS FOR ALL NINE LINES, SIDE BY SIDE:

$X^2 + X + 5$	$4 \quad 2 \quad 2$
$2X^2 + 5$	$5 \quad 2 \quad 1$
$2X^2 + 7$	$6 \quad 2 \quad 1 \quad 2$
$2X^2 + 11$	$10 \quad 2 \quad 1 \quad 4$
$2X^2 + 11$	$11 \quad 2 \quad 1 \quad 3$
$2X^2 + 17$	$16 \quad 2 \quad 1 \quad 4 \quad 1 \quad 6$
$2X^2 + 19$	$18 \quad 2 \quad 1 \quad 3 \quad 1 \quad 4$
$2X^2 + 29$	$29 \quad 2 \quad 1 \quad 1 \quad 2 \quad 1 \quad 5 \quad 1 \quad 6$
$X^2 + 41$	$40 \quad 2 \quad 1 \quad 4 \quad 1 \quad 6 \quad 1 \quad 8 \quad 1 \quad 10$

FIGURE 102.

NOTICE THAT THE  $X^2 + X + C$  TYPE LINES ARE THE ONES WITH THE EVEN-NUMBERED PRIME GROUPINGS AFTER THE INITIAL "BREAK". AND, OF COURSE, THE INITIAL BREAK IN EACH CASE IS SIGNALLED WITH TWO NON-PRIMES, WHILE THE SPACING AFTER THAT BETWEEN PRIME GROUPINGS, FOR THE DURATION OF THE PATTERN, IS ONE NON-PRIME. FINALLY, THESE PATTERNS EXTEND IN EACH CASE TO ROUGHLY  $X = 2C$  WHERE  $C$  IS THE CON-

## STANT AT THE END OF THE APPROPRIATE FORMULA.

### 17. LINES GALORE!

IT RECENTLY OCCURRED TO ME TO TRY NEW ARRAY VARIATIONS TO SEE IF ANY MORE LINES COULD BE FOUND. I HAD NEVER LOOKED AT THE ARRAY BASED ON COUNTING IN THIS MANNER:

1	2	3	4	5		
6	7	8	9	10	11	12
ETC.						

FIGURE 103.

OR FOR THAT MATTER AT ANY ARRAYS BASED ON "JUTTING" MORE THAN TWO SPOTS TO THE RIGHT WITH EACH ARRAY LINE, KEEPING THE "JUT" CONSTANT! WELL, THERE ARE MANY MORE LINES TO BE FOUND IN THIS WAY.

LET'S TAKE JUTTING 3 FIRST,

BY COUNTING AS IN FIGURE 103, EVIDENCE OF SEVERAL UNBROKEN LINES OF PRIMES APPEARS. SEE FIGURE 104. THERE IS ONLY ONE PROBLEM - INSTEAD OF SPANNING THE ARRAY FROM THE "HYPOTENUSE" SOUTHWEST TO THE LEFT EDGE, THESE LINES EXTEND SOUTHEAST AND STOP IN THE MIDDLE OF NOWHERE. THE ENDPOINTS ARE ALIGNED, IT IS TRUE, BUT THIS WILL NEVER DO.

IS THERE ANY WAY TO RECTIFY THIS SITUATION? ANY WAY TO GENTLY SHIFT THE LINES TO THE SOUTHWEST WITHOUT DISTURBING THEIR STRUCTURE? YES.

REMEMBERING HOW ORIGINALLY "THE OTHER FOUR LINES" WERE ORIENTED VERTICALLY WITH ENDPOINTS ALIGNED ON AN IMAGINARY LINE EXTENDING SOUTHEAST, WHEN THE COUNTING WAS AS IN FIGURE 63, WHILE THEY BEHAVED "PROPERTY" WHEN THE COUNTING WAS ALTERED SLIGHTLY AS IN FIGURE 65, I THOUGHT ABOUT TRYING SOMETHING SIMILAR.

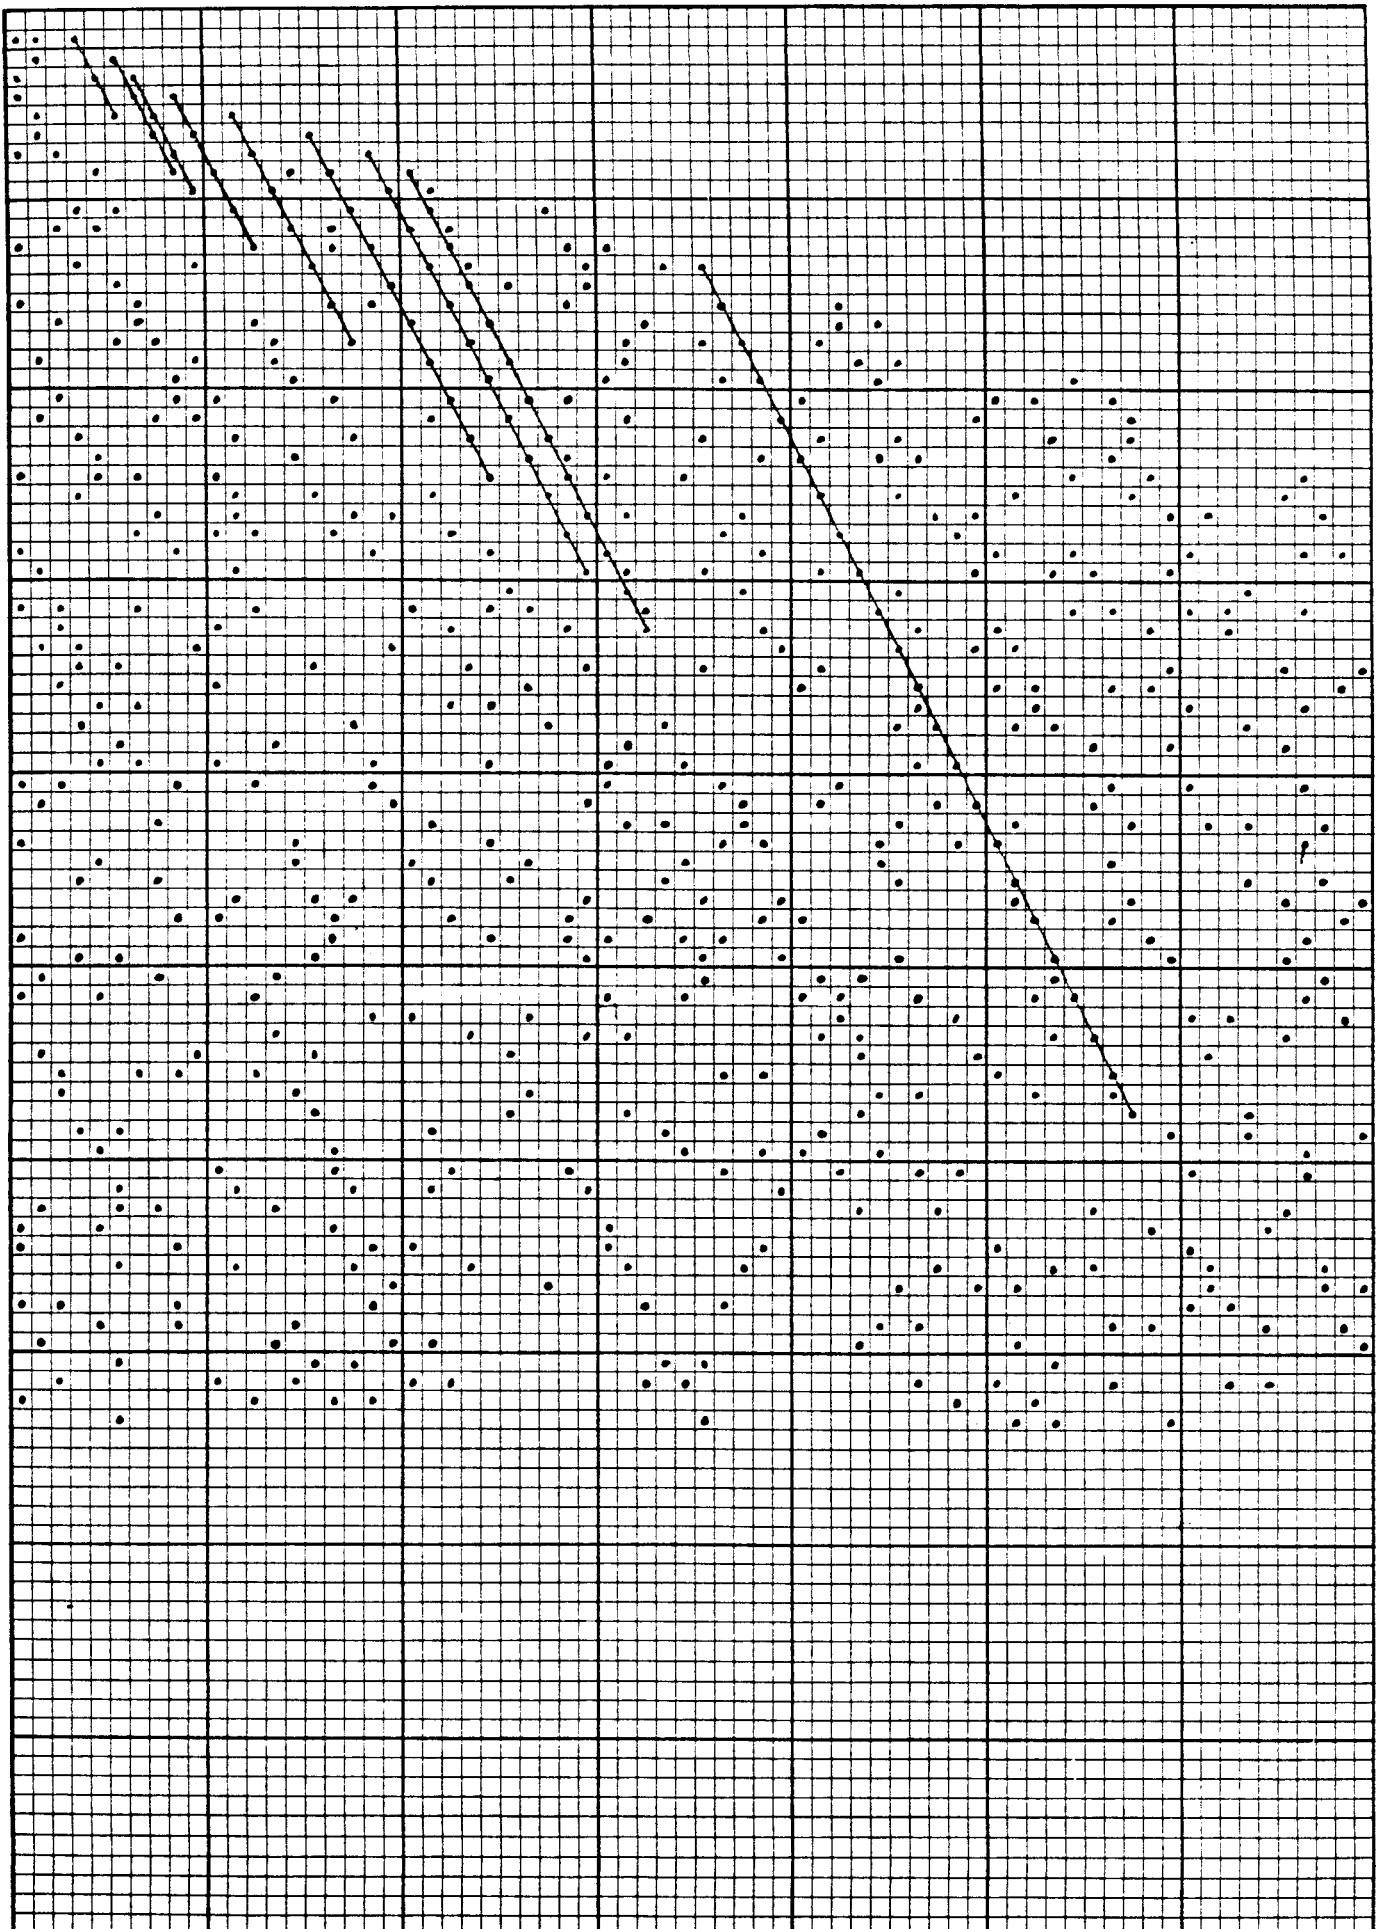

BY CHANGING THE COUNTING SCHEME ONLY SLIGHTLY TO:

1	2						
3	4	5	6	7			
8	9	10	11	12	13	14	15
ETC.							

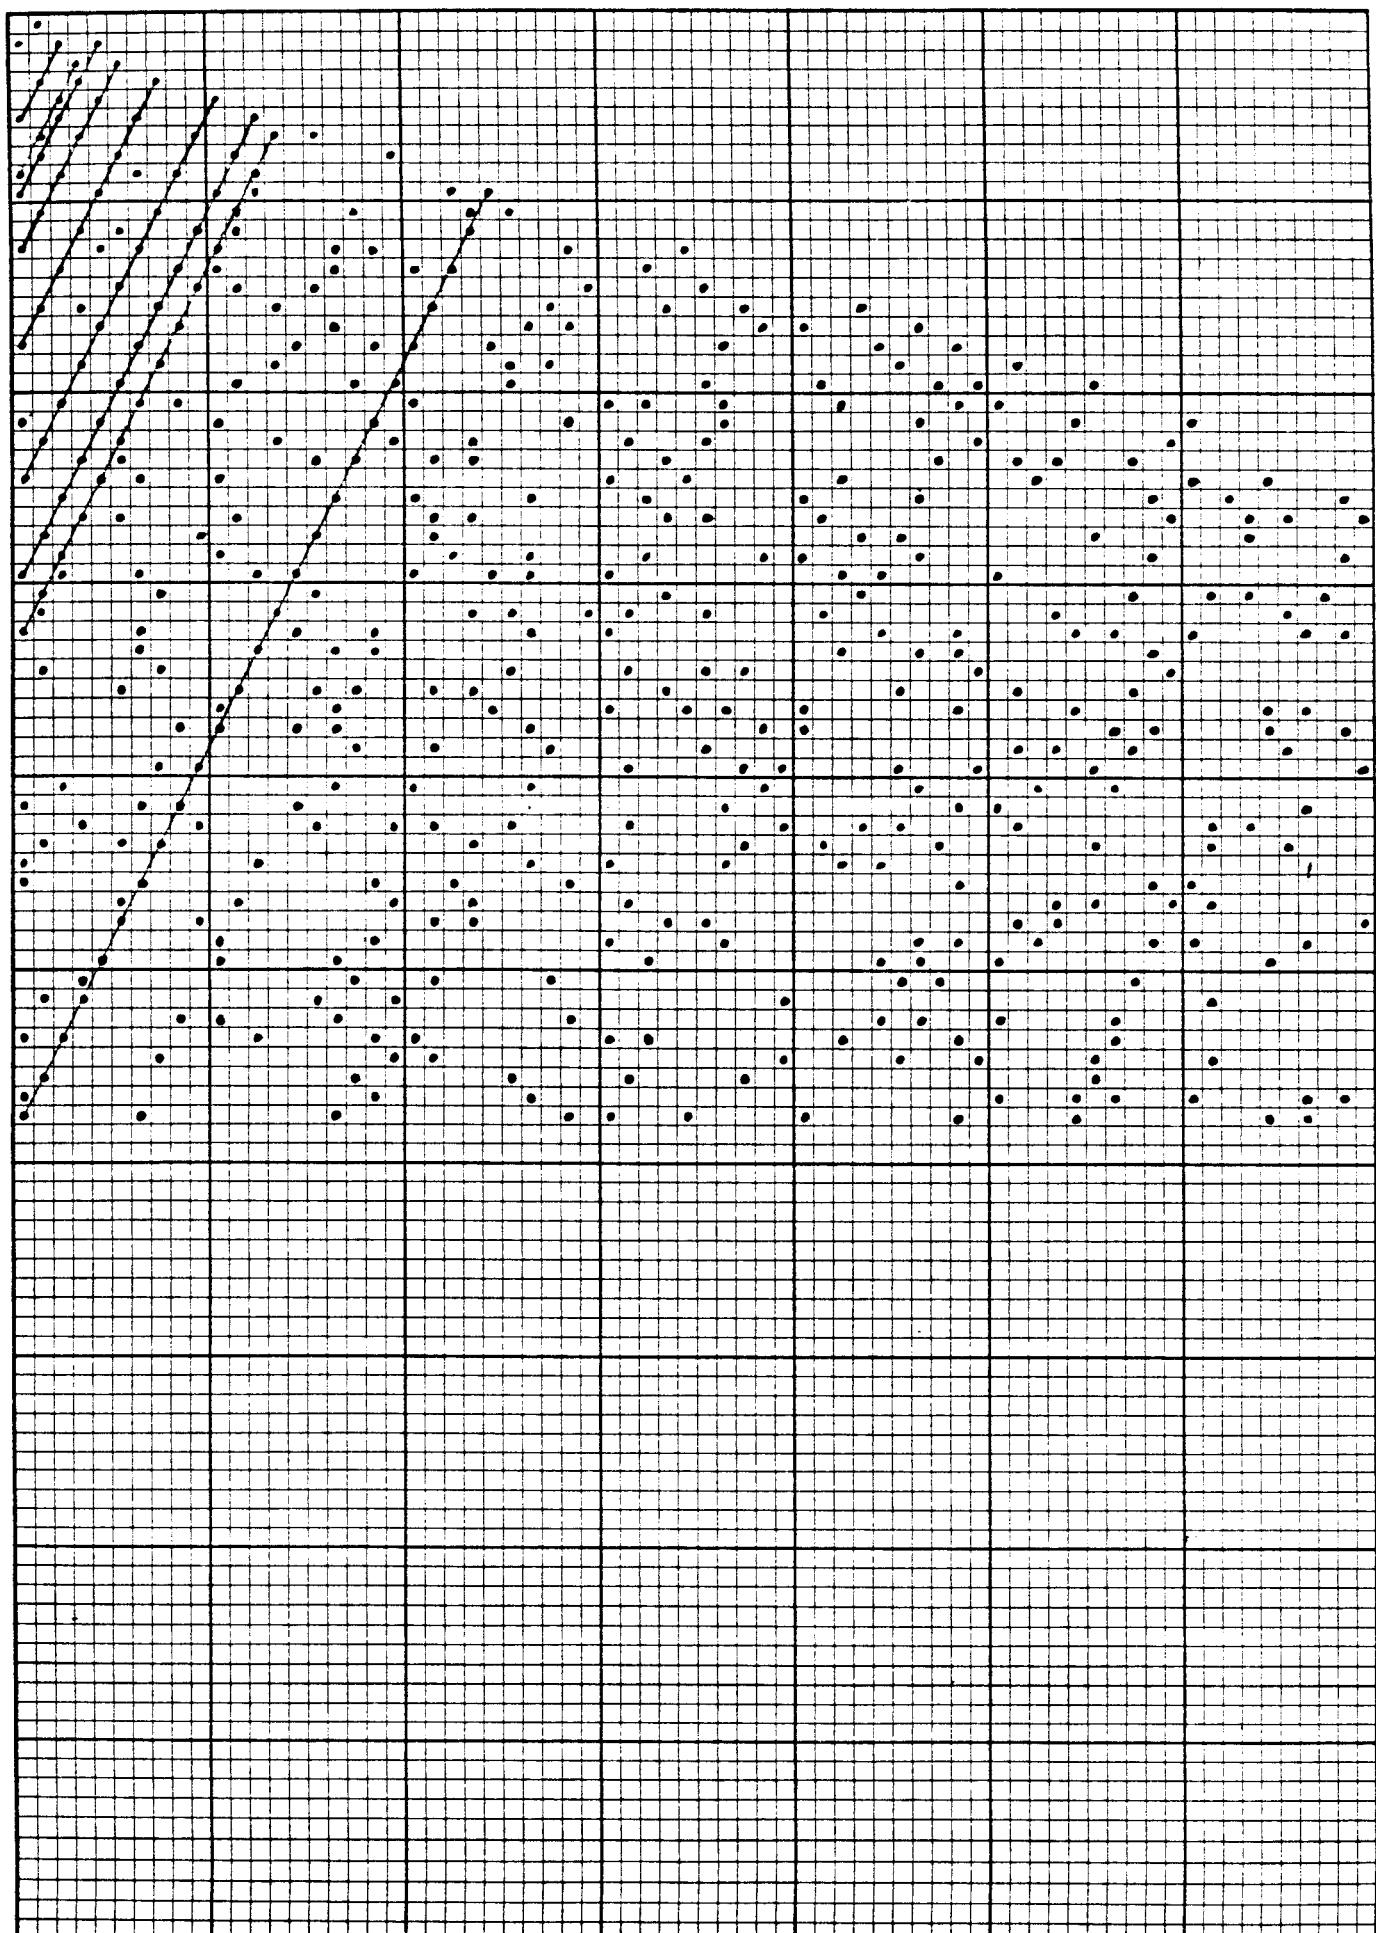

FIGURE 105.

WE GET THE DESIRED EFFECT. SEE FIGURE 106.

ALL TOLD THERE ARE NINE LINES IN THE ARRAY OF FIGURE 106, AND THEY FORM A FAMILY VERY SIMILAR TO THE ORIGINAL FAMILY OF NINE LINES. THE NINE NEW FORMULAS ARE:

CITADEL NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

$6x^2 + 6x + 5$   
 $6x^2 + 6x + 5$   
 $6x^2 + 6x + 7$   
 $6x^2 + 6x + 7$   
 $6x^2 + 6x + 11$   
 $6x^2 + 6x + 13$   
 $6x^2 + 6x + 17$   
 $6x^2 + 17$   
 $6x^2 + 31$

FIGURE 107.

AS WAS THE CASE WITH THE ORIGINAL NINE LINES, THE NORTHEAST ENDPOINTS OF THESE LINES ARE NOT THE VALUES OF THE FUNCTIONS WHEN  $x = 0$ . ALSO, AS WITH THE ORIGINAL NINE LINES, THE SOUTHWEST ENDPOINTS OF THESE NEW LINES ARE THE LAST VALUES OF THE FUNCTIONS BEFORE THE STRING OF PRIMES IS BROKEN. IN OTHER WORDS, IF  $6x^2 + 6x + 11$  IS PRIME FOR NINE CONSECUTIVE VALUES OF  $x$ , FROM 0 THROUGH 8, ITS LINE ON THE ARRAY IN FIGURE 106 WILL HAVE SOMEWHAT FEWER THAN NINE DOTS IN IT, BUT THE LAST DOT GOING DOWN THE LINE WILL CORRESPOND TO THE VALUE OF  $6x^2 + 6x + 11$  FOR  $x = 8$ . (THAT LAST DOT WOULD REPRESENT THE NUMBER 443.) BY THE SAME TOKEN, THE LINE REPRESENTING  $6x^2 + 6x + 31$  WOULD HAVE FEWER THAN 29 DOTS, BUT THE LAST DOT IN IT WOULD CORRESPOND TO THE LAST PRIME IN THE UNBROKEN STRING GENERATED BY  $6x^2 + 6x + 31$ , THAT OF  $x = 28$ . (THAT LAST DOT WOULD REPRESENT THE NUMBER 4903.)

## 117 -

WHAT ABOUT ARRAYS WITH JUTS OF GREATER THAN 3? YES, MORE LINES ARE THERE.

BY JUTTING 4 AND STARTING WITH A TOP OF ONE SPOT THUS:

1	2	3	4	5	6						
	7	8	9	10	11	12	13	14	15		

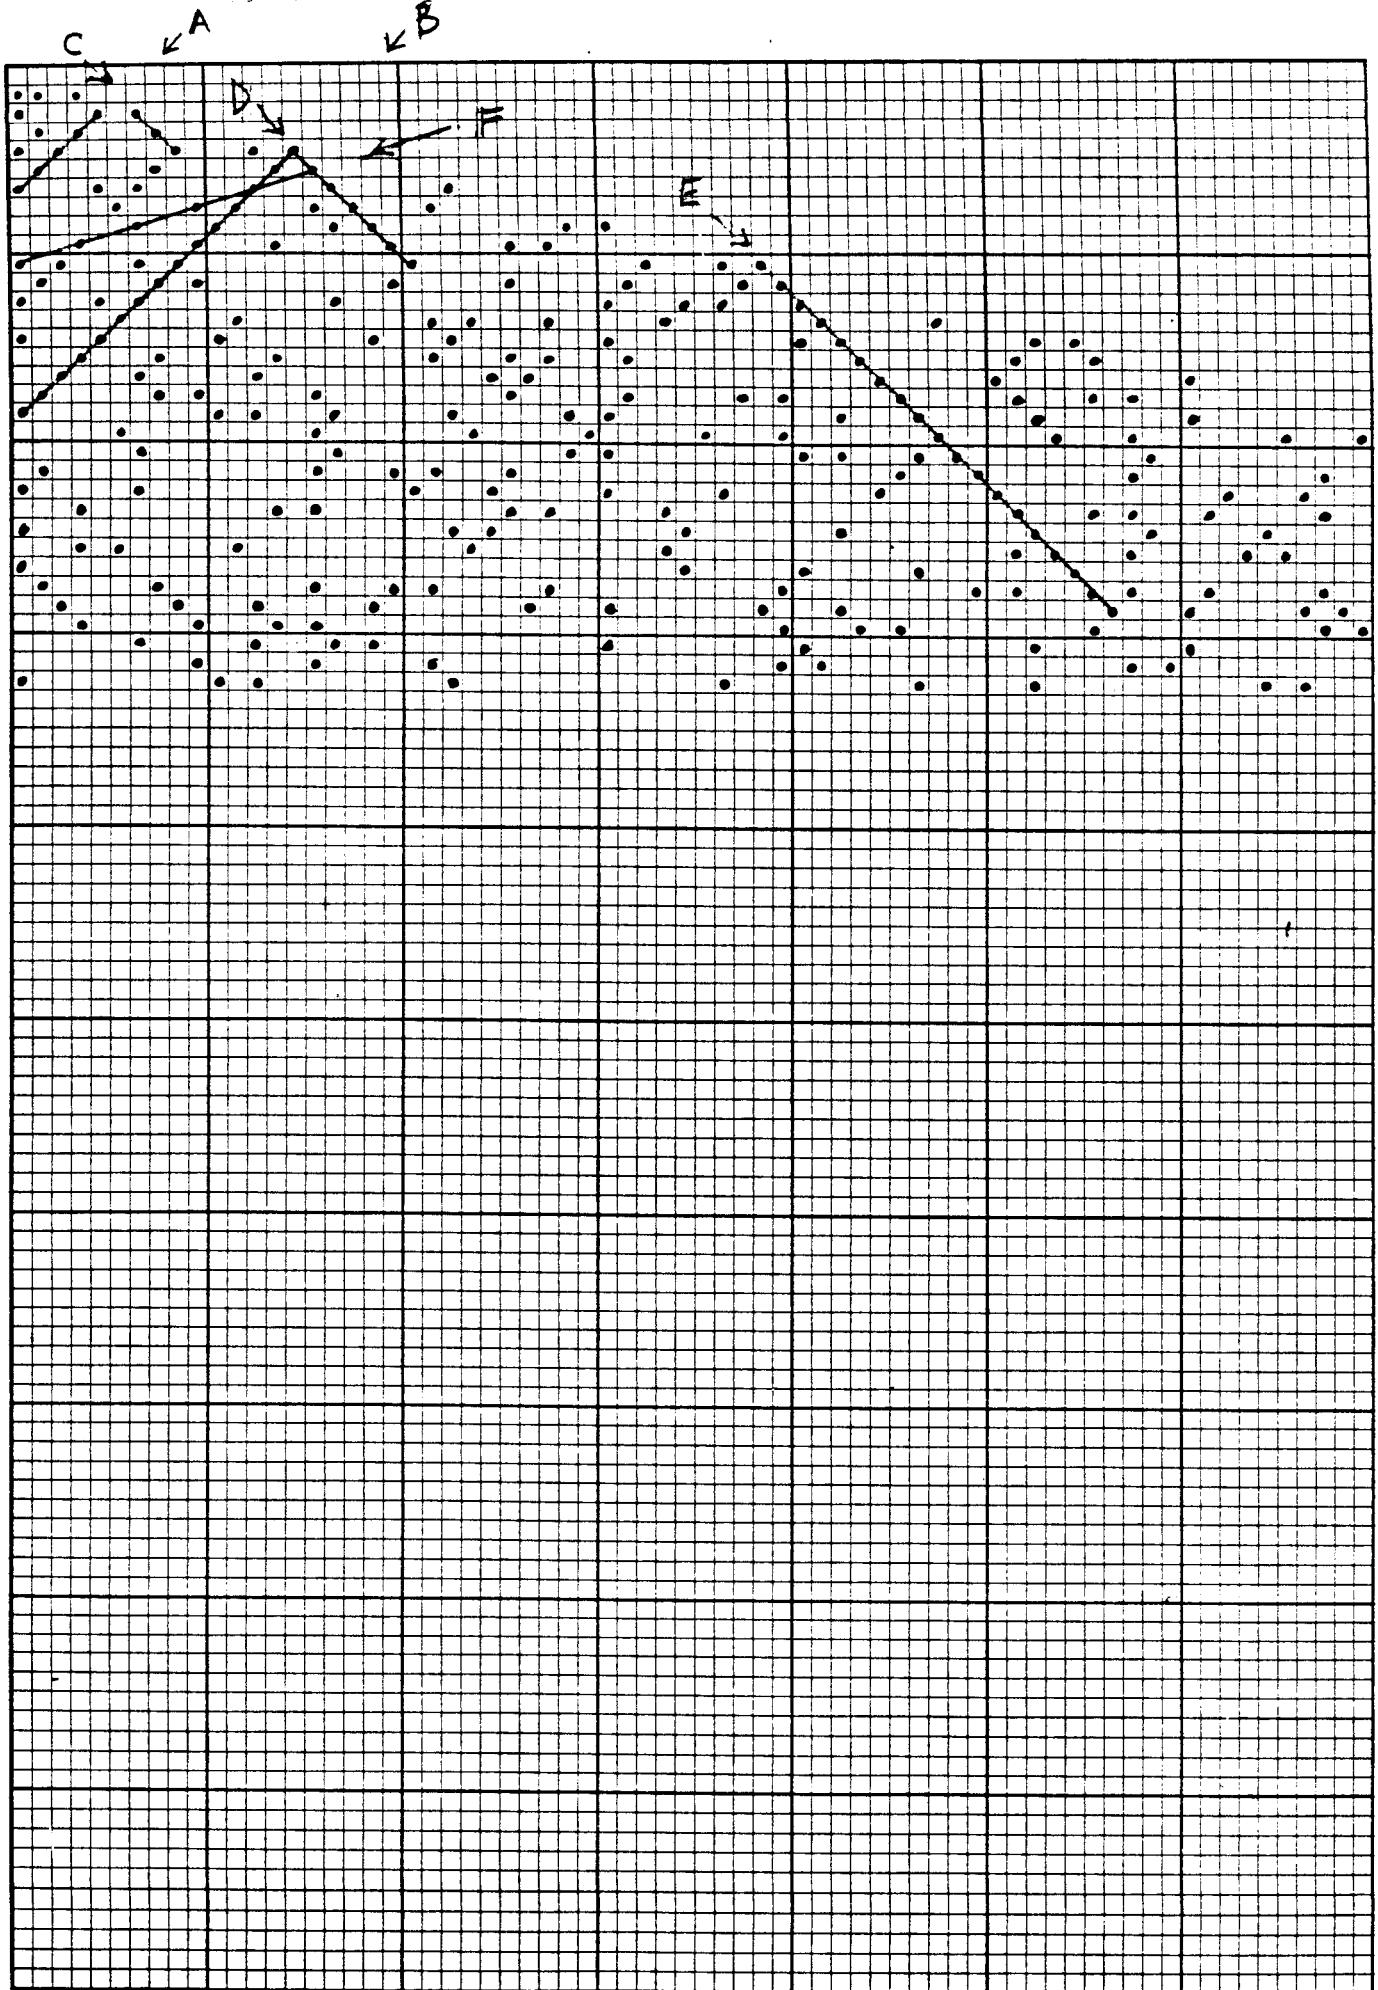

ETC.

FIGURE 108.

A PAIR OF LINES APPEARS, BUT THEY ARE OUR OLD FRIENDS  $2x^2 + 2x + 7$  AND  $2x^2 + 2x + 19$  (SEE FIGURE 109, LINES A AND B), WHILE THREE PARALLEL STRINGS HEADING SOUTHEAST WHOSE SOUTHERN ENDPOINTS LINE UP ALSO CATCH THE EYE, AND ARE OLD FRIENDS  $2x^2 + 5$ ,  $2x^2 + 11$ , AND  $2x^2 + 29$  (FIGURE 109, LINES C, D, AND E). ALSO, AT A DIFFERENT SLOPE THAN THE  $2x^2 + 2x + C$  LINES IS A SMALL LINE OF 6 DOTS HEADING SOUTHWEST WHICH TURNS OUT TO BE ONLY ANOTHER STRETCH OF  $2x^2 + 29$  (LINE F IN FIGURE 109).

FOR A JUT OF 5 AND A TOP OF 1 SPOT, ONLY ONE SHORT LINE APPEARS, TO BE DISCUSSED IN A MOMENT. IN ADDITION, A FEW PARABOLAS OF DOTS ARE EVIDENT. THESE CURVES BECOME STRAIGHT LINES WHEN THE JUT IS 6. THEIR DISCUSSION WILL ALSO BE DEFERRED (UNTIL JUT = 6 IS DISCUSSED).

THE LITTLE LINE MENTIONED A MOMENT AGO IS A BIT TROUBLESOME. IT CONFORMS IN TWO WAYS TO THE DEFINITION OF A LINE OF PRIMES, BUT

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

IN TWO OTHER WAYS IT DOES NOT. TO BE EXPLICIT, SO FAR PRIME LINES HAVE BEEN UNBROKEN STRAIGHT LINES OF EVENLY SPACED DOTS (REPRESENTING PRIME NUMBERS) AND THESE STRINGS HAVE SPANNED THE GRAPHS FROM THE "HYPOTENUSE" OF THE TRIANGULAR ARRAYS ALL THE WAY SOUTHWEST UNTIL THEY REACHED THE "WESTERN" EDGE OF THE GRAPHS. IN ADDITION, THE FORMULAS FOR THE PRIME SEQUENCES GENERATING THE LINES HAVE BEEN OF THE FORM  $AX^2 + BX + C$  OR  $AX^2 + C$  WHERE  $C$  IS PRIME. ALSO, THE FIRST VALUE OF  $X$  FOR WHICH THE FUNCTIONS YIELD A PRIME HAS ALWAYS BEEN ZERO AND THE LAST HAS BEEN NEAR  $C$ .

THE LITTLE LINE IN THE ARRAY WITH TOP = 1 AND JUT = 5 IS AN UNBROKEN STRING AND SPANS THE ARRAY FROM THE HYPOTENUSE SOUTHWEST TO THE WESTERN EDGE. IT DOES NOT, HOWEVER, CONFORM TO THE OTHER CRITERIA. ITS FORMULA IS  $10X^2 - 4X + 5$  AND  $X$  RANGES FROM -4 THROUGH 4.

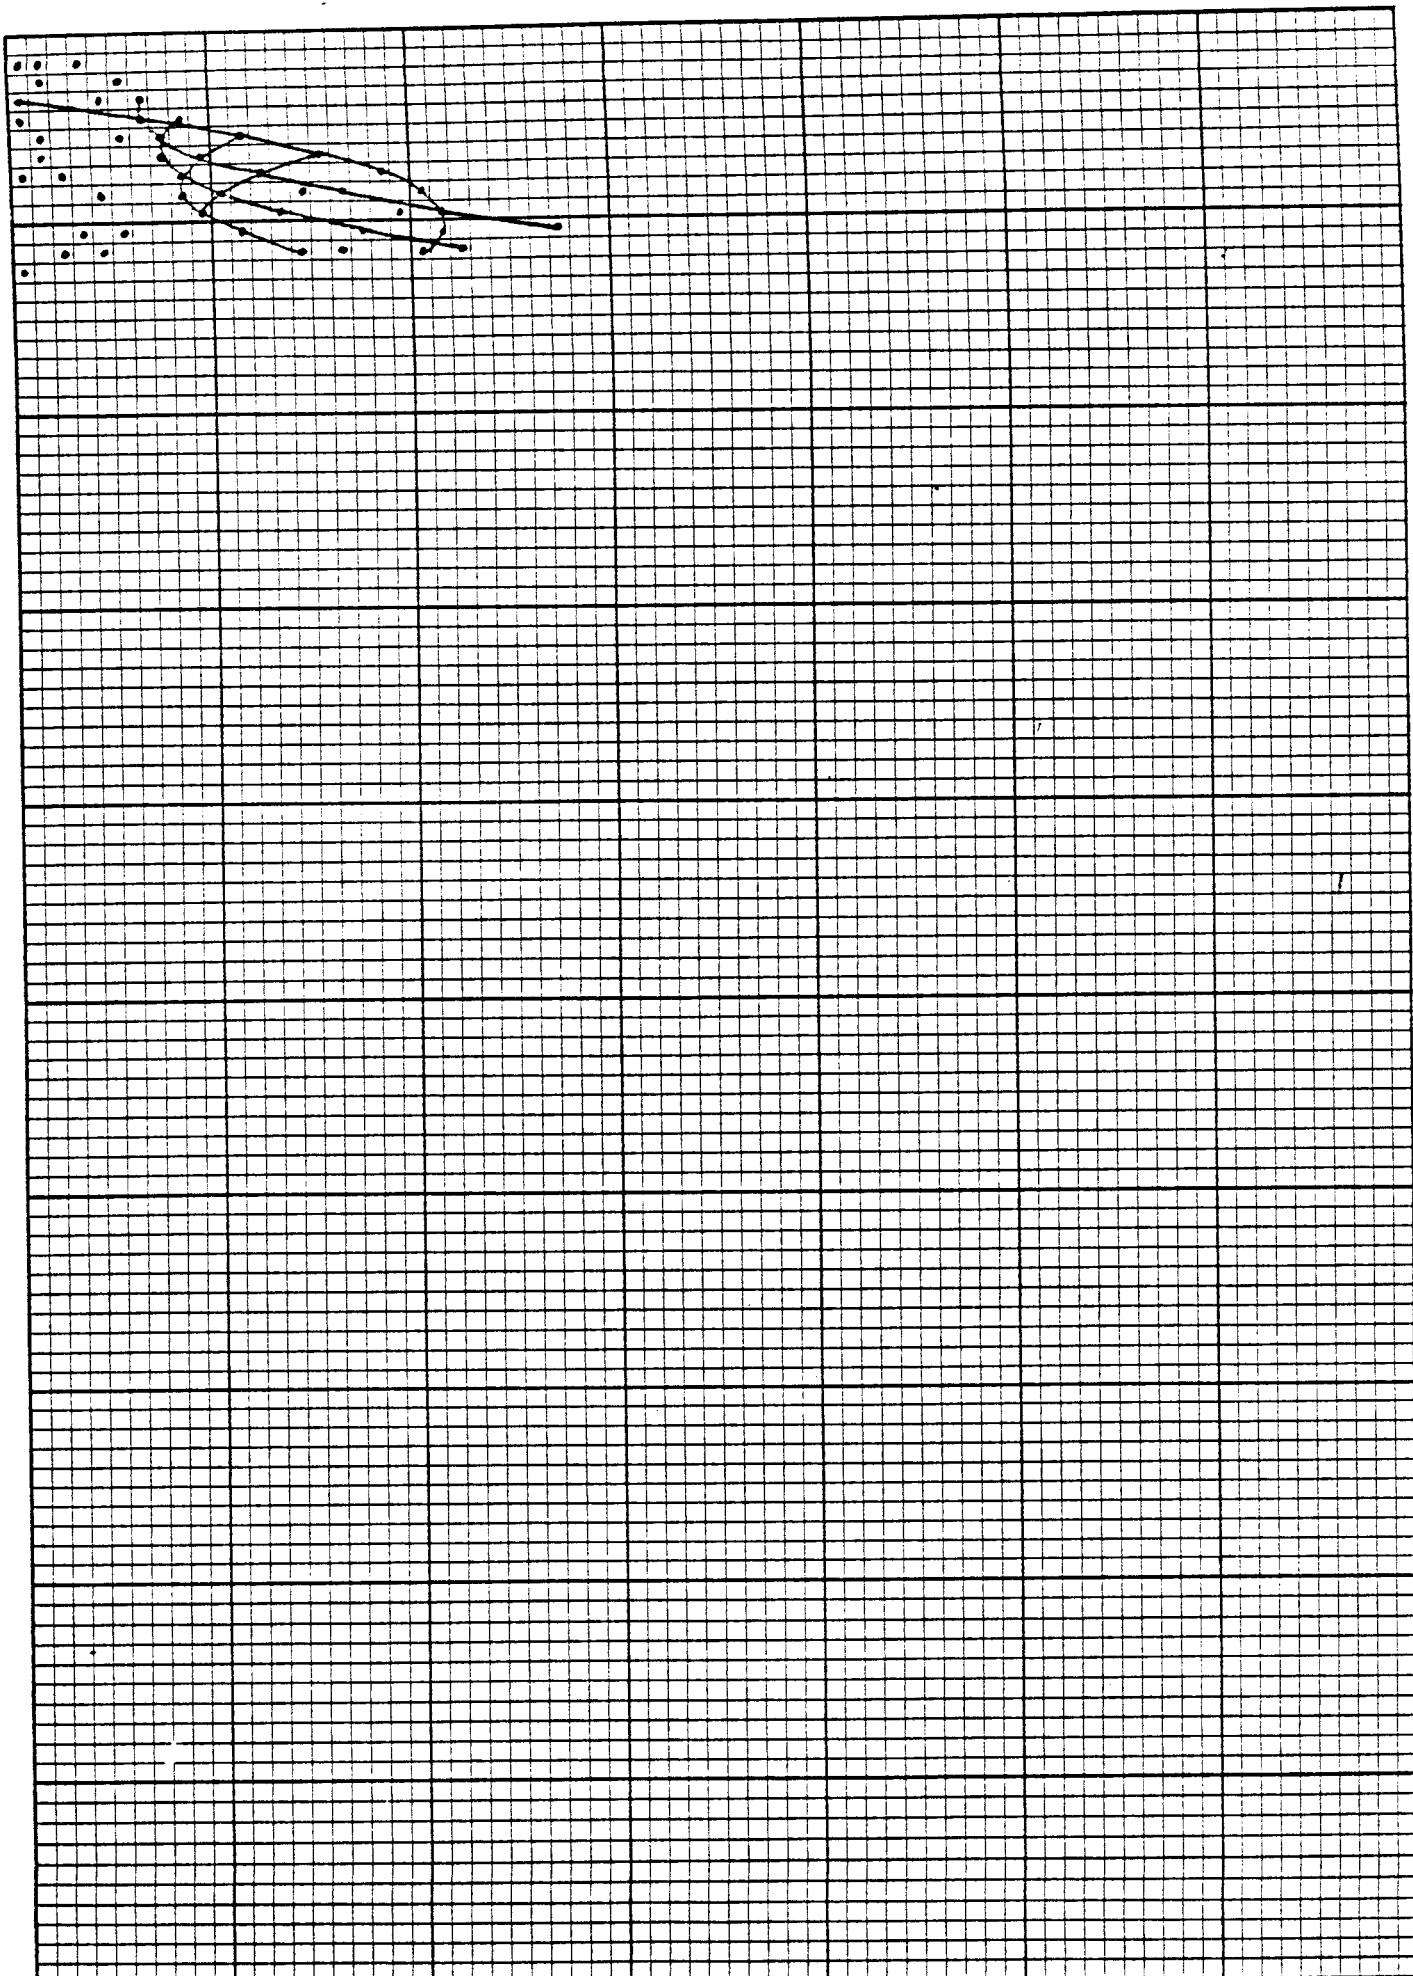

TO RECONCILE THE TWO TYPES OF PRIME LINE IS NO REAL PROBLEM, THOUGH. FIRST, A FORMULA NEED ONLY BE A QUADRATIC OF FORM  $AX^2 + BX + C$ . FOR THE ORIGINAL FORMULAS, EITHER  $B$  WAS EQUAL TO A OR  $B$  WAS ZERO, AND A, B, AND C WERE NON-NEGATIVE. THOSE RESTRICTIONS NEED NOT HOLD. FURTHERMORE, THE RANGE OF  $X$  WAS FROM ZERO TO SOME POSITIVE NUMBER. IT CAN NOW EXTEND FROM ANY INTEGER TO ANY OTHER, FOR EXAMPLE FROM -4 TO 4. IT TURNS OUT THAT THE RANGE OF  $X$  FOR ANY OF THE ORIGINAL FORMULAS EXTENDS JUST AS FAR BELOW ZERO AS IT DOES ABOVE ZERO. FOR EXAMPLE, TAKE  $X^2 + X + 11$ . THE VALUE OF THIS EXPRESSION FOR  $X = 1$  IS 13. THE VALUE FOR  $X = -2$  IS ALSO 13. THE VALUE FOR  $X = 2$  IS 17 WHILE THAT FOR  $X = -3$  IS ALSO 17, AND SO ON. SO, THE ACTUAL RANGE OF  $X$  IN THE ORIGINAL FORMULAS FOR WHICH THE FUNCTIONS YIELD A PRIME IS TWICE WHAT WAS STATED. FOR EXAMPLE,  $X^2 + X + 41$  YIELDS A PRIME FOR EVERY WHOLE VALUE OF  $X$  FROM -40 THROUGH 39, OR FOR 80 STRAIGHT VALUES OF  $X$ . OF COURSE NO NEW PRIMES ARE GENERATED BY THE NEGATIVE  $X$ 'S, AT LEAST FOR THE ORIGINAL FORMULAS. AS YOU WILL SEE, THERE ARE OTHER INSTANCES OF THE NEW TYPE OF FORMULA GENERATING "SPANNING DIAGONALS", FOR WHICH NEGATIVE VALUES OF  $X$  ARE NOT TRIVIAL.

LOOKING BACK, I NOW REMEMBER THAT WHEN I FIRST PLOTTED JUT = 3 TOP = 1 (WHICH LED ME EVENTUALLY TO NINE NEW STRAIGHT LINES, YOU WILL RECALL), THE FIRST THING THAT CAUGHT MY EYE WAS NOT THE BEGINNINGS OF THE STRAIGHT LINES BUT A SET OF PARABOLAS FITTING TOGETHER. THERE WERE FOUR OPENING TO THE RIGHT, WHICH TURNED OUT TO BE  $2X^2 + 2X + 7$ ,  $2X^2 + 11$ ,  $2X^2 + 19$ , AND  $2X^2 + 29$ , AND ONE WHICH OPENED TO THE LEFT. SEE FIGURE 110. THIS LAST ONE HAS THE FORMULA  $X^2 + X - 43$  AND  $X$  HAS THE RANGE 0 THROUGH 17. 18 STRAIGHT PRIMES IS A NICE STRING. AFTER A LITTLE LOOKING I FOUND A FEW MORE RELATED STRINGS:

$$\begin{aligned} X^2 + X - 73 && -1 < X < 24 \\ X^2 + X - 109 && -1 < X < 28 \\ X^2 + X - 169 && 0 < X < 25 \\ 2X^2 + 2X - 113 && -1 < X < 22 \end{aligned}$$

NOTE THAT IN  $X^2 + X - 169$   $C$  IS NOT PRIME.

TO WRAP UP THIS ASIDE, THE BIGGEST GENERATORS OF CONSECUTIVE

CITADEL NO. 542 - CROSS SECTION - 10 SQUARES TO INCH

PRIMES I HAVE FOUND SO FAR BESIDE  $x^2 + x + 41$  ARE QUADRATICS OF THE "NEH" TYPE, WITH B NOT = A OR 0, AND WITH X RANGING FROM NEGATIVE VALUES TO POSITIVE ONES. THE TWO LARGEST ARE:

$$\begin{aligned} 25x^2 - 15x + 43 & \quad -8 < x < 25 \\ \text{AND } 16x^2 + 28x + 53 & \quad -11 < x < 21. \end{aligned}$$

THE FIRST FORMULA GENERATES THE BIG PRIME RIB FEATURED IN FIGURE 62. THE SECOND WAS ALSO FOUND THROUGH THE STUDY OF PRIME RIBS.

## 18. JUTS OF 6 AND HIGHER

### THE ARRAY BASED ON COUNTING

1  
2 3 4 5 6 7 8  
9 10 11 12 13 14 15 16 17 18 19 20 21  
ETC.

FIGURE 111.

REVEALS NEW LINES:

$$\begin{aligned} 3x^2 + 3x + 5 & \quad -1 < x < 4 \\ 3x^2 + 3x + 11 & \quad -1 < x < 10 \\ 3x^2 + 3x + 23 & \quad -1 < x < 22. \end{aligned}$$

FIGURE 112.

SEE FIGURE 113.  
THESE WERE THE PARABOLAS OF JUT=5.

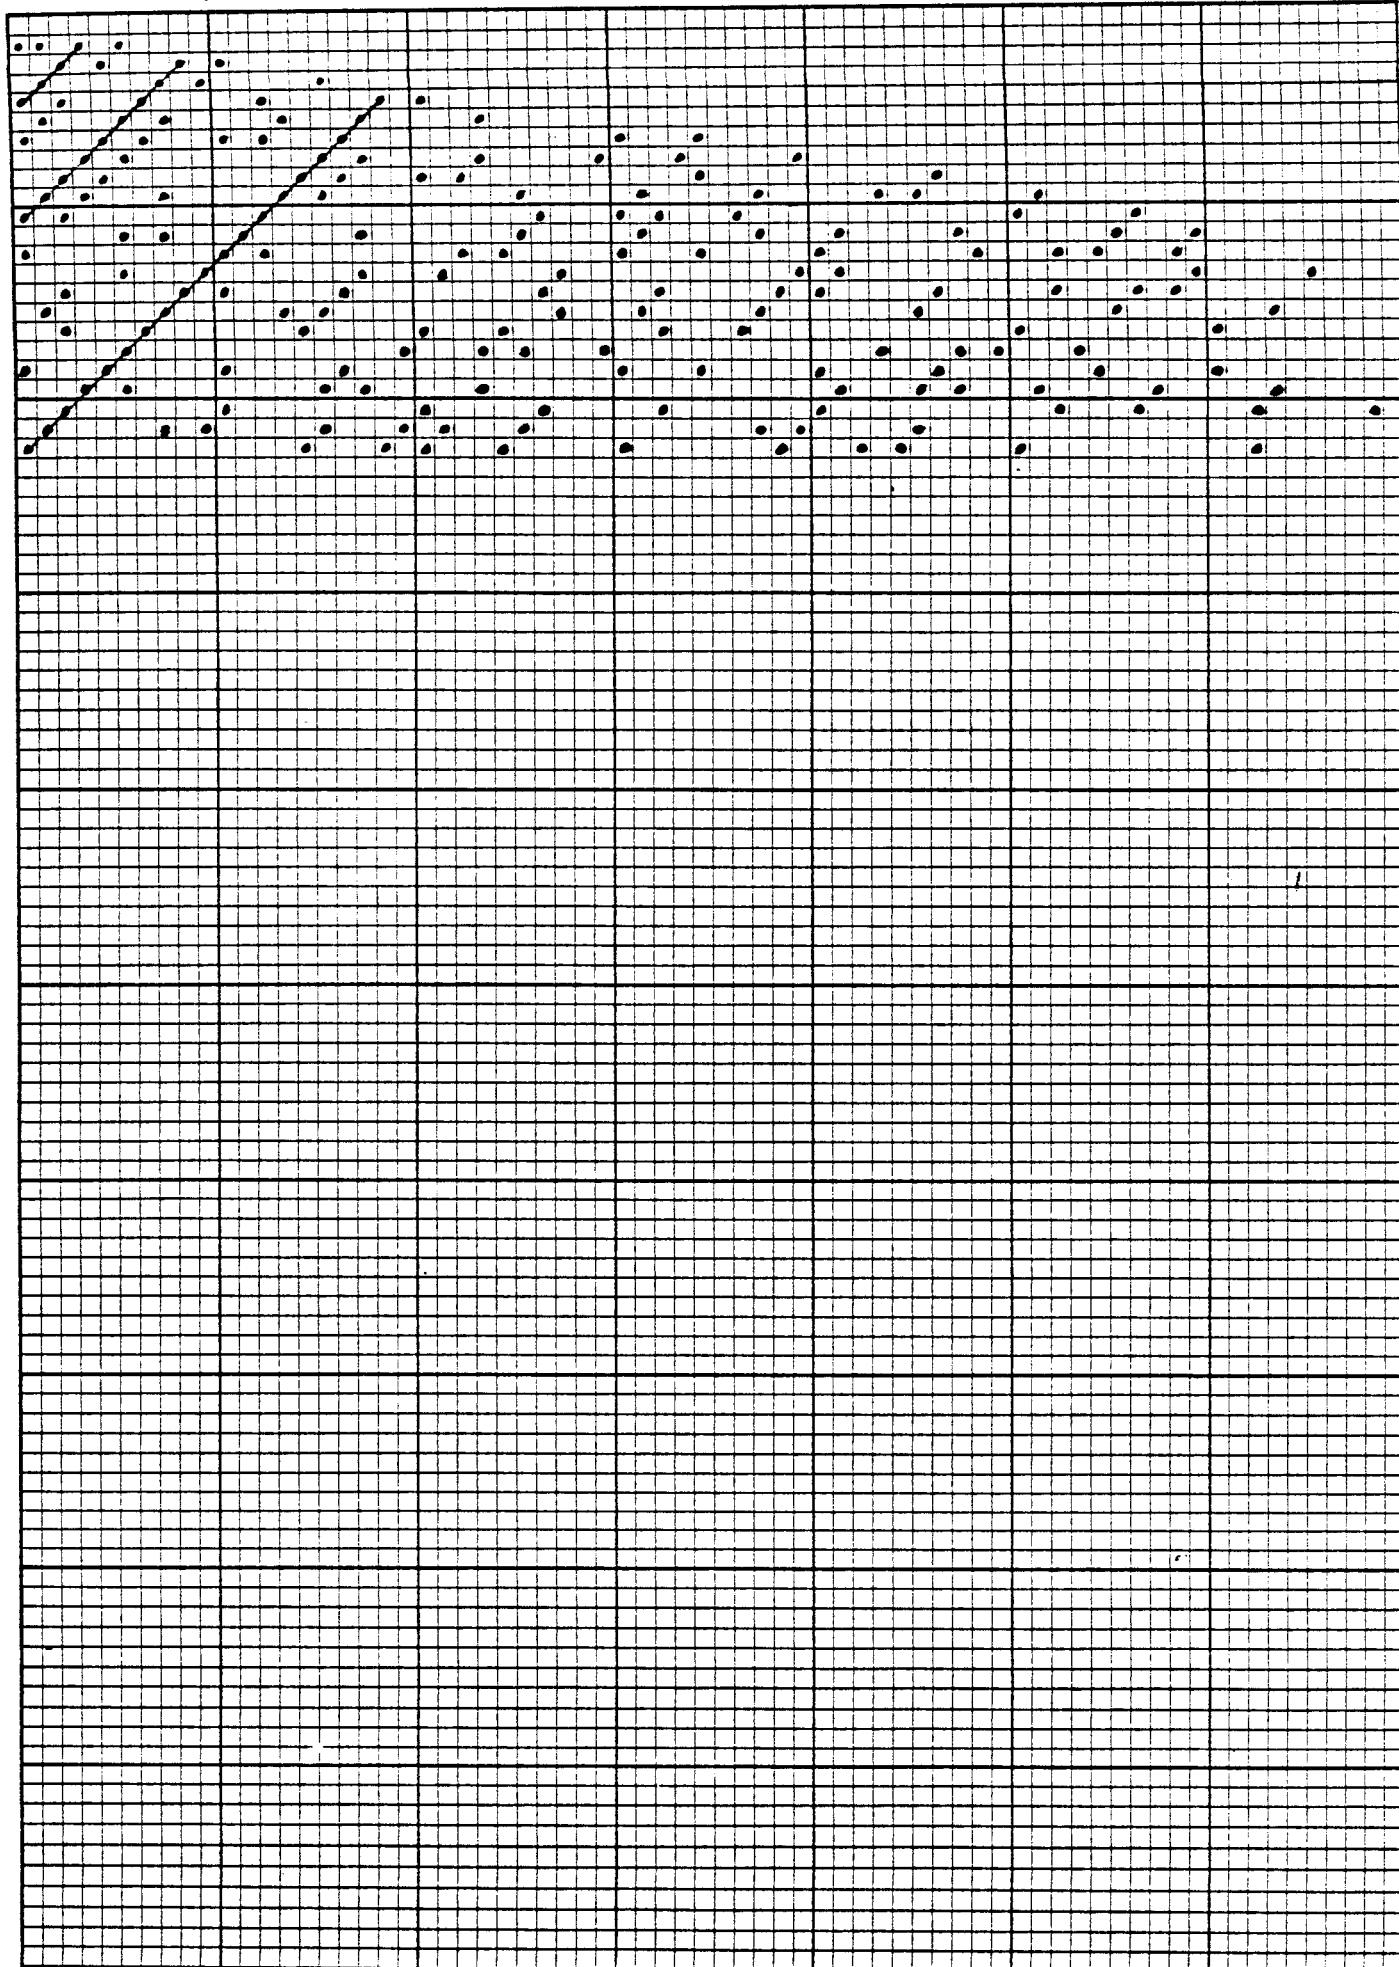

FOR JUT=7 AND TOP=1, ONE STRAIGHT LINE APPEARS:  $14x^2 + 8x + 7$ ,  $-7 < x < 6$ . IN ADDITION, ONE RATHER FERTILE PARABOLA,  $4x^2 + 2x + 17$ , WHICH YIELDS 16 STRAIGHT PRIMES FOR  $-9 < x < 8$ , APPEARS.

BEFORE WE RESUME THE DISCUSSION OF LARGER JUTS, ANOTHER SIDE-TRACK MUST BE EXPLORIED, AS YOU WILL SEE:

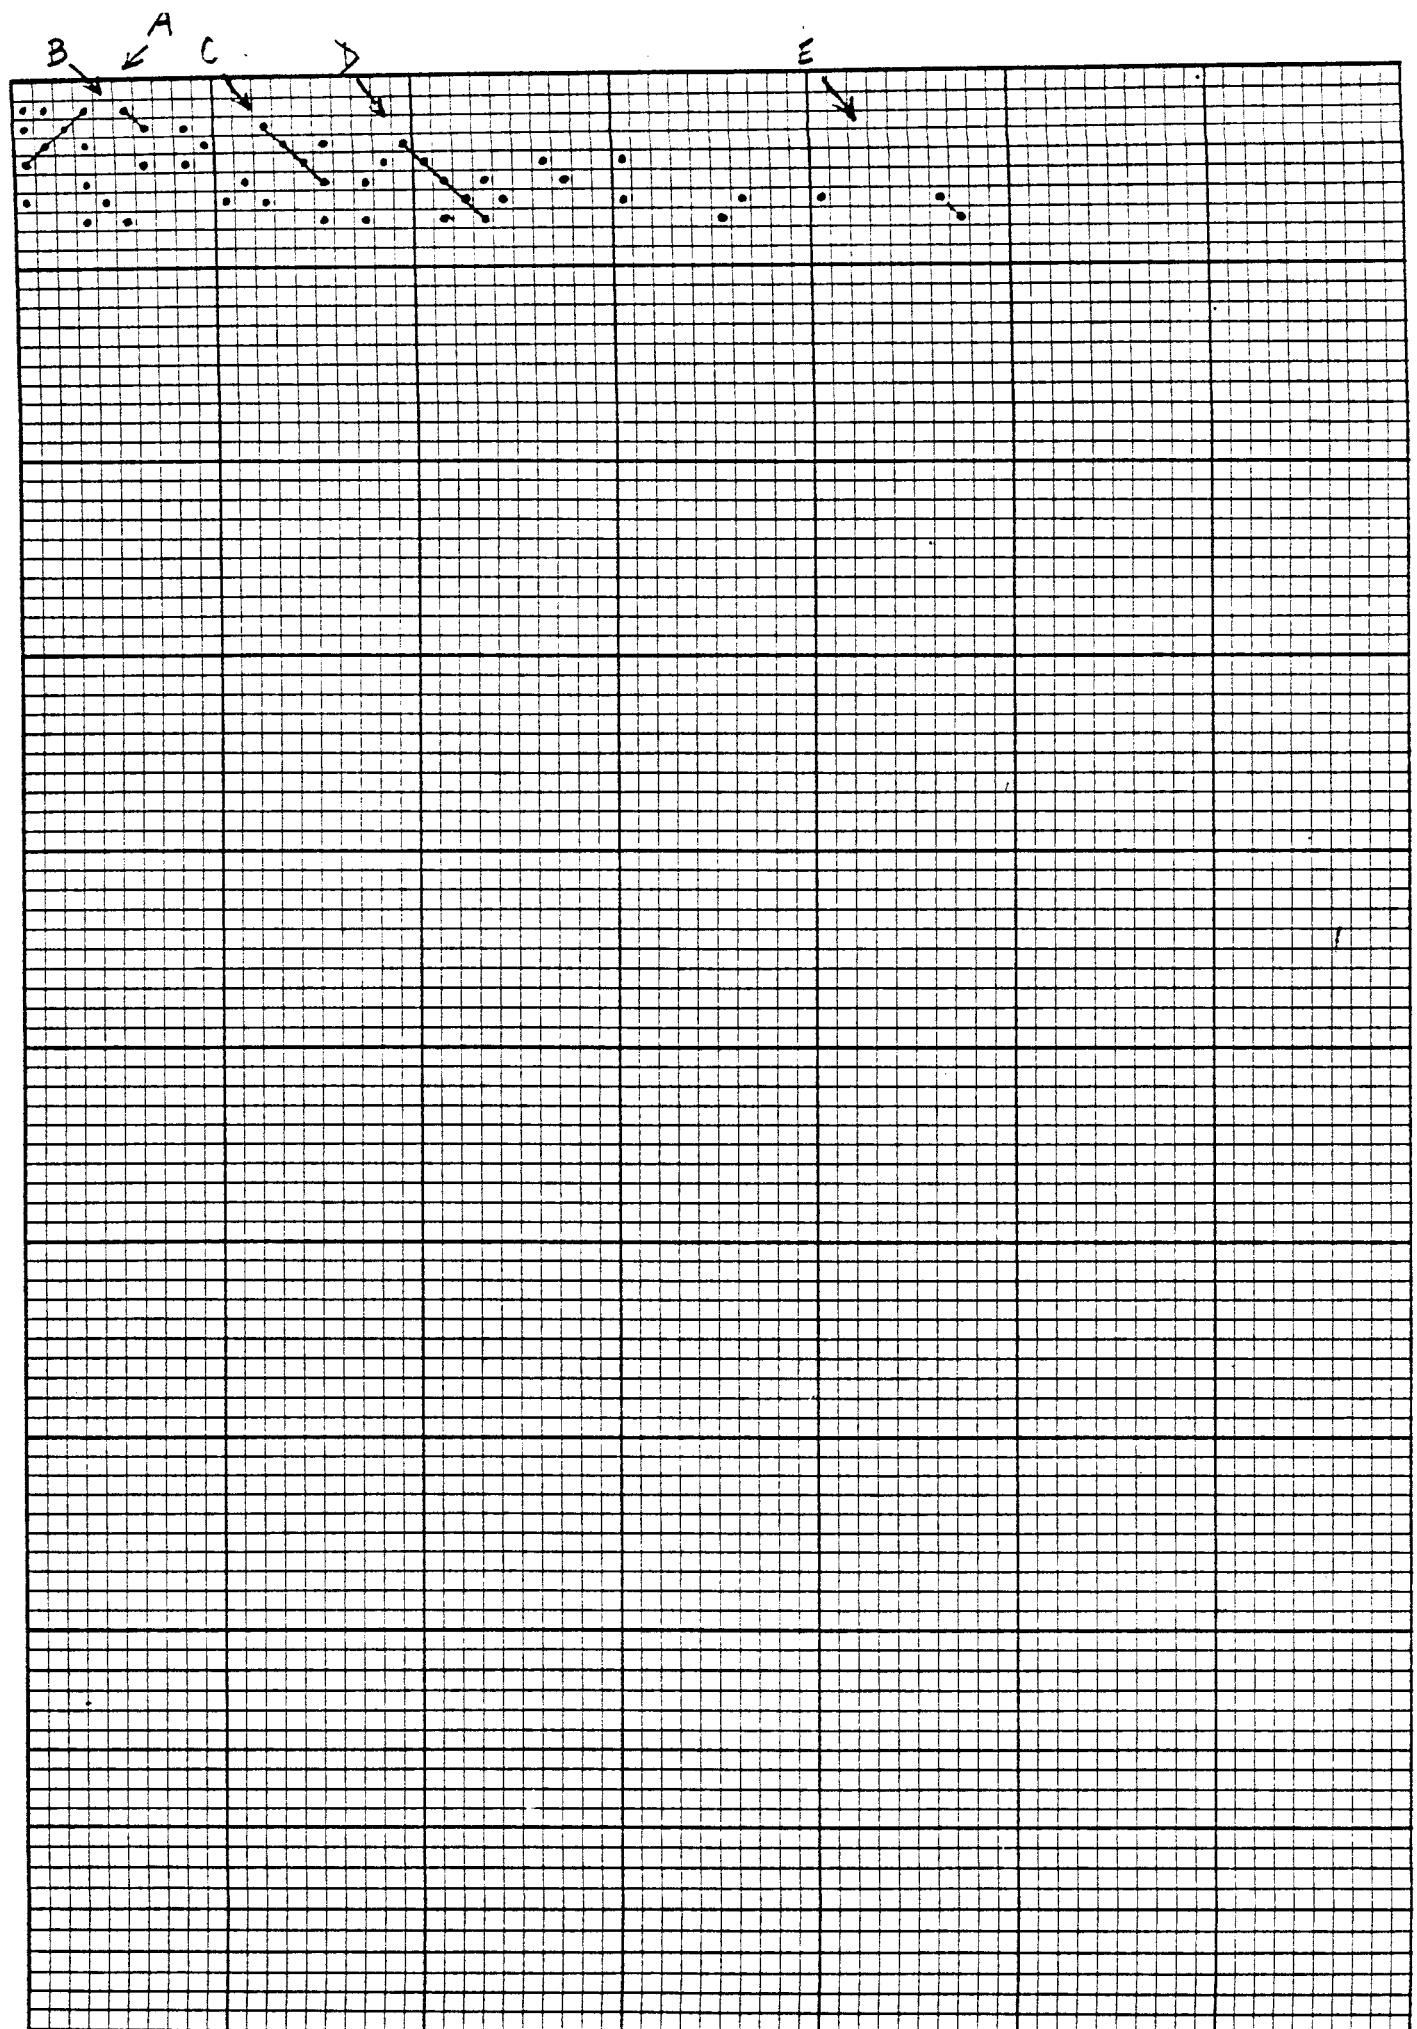

## 19. WELL I'LL BE! (OLD FRIENDS IN DISGUISES)

WHEN I LOOKED AT THE ARRAY FOR JUT=8 TOP=1 TO DISCUSS THAT NEXT, JUST NOW, BESIDES SEEING THE ONE PALTRY SPANNING DIAGONAL THERE,  $4x^2 + 4x + 5$ , ONLY FOUR DOTS IN SPAN (SEE FIGURE 114, LINE A), I NOTICED A FEW LINES OF DOTS EXTENDING PARALLEL TO EACH OTHER IN A SOUTHEAST DIRECTION (FIGURE 114, LINES B, C, AND D). LOOKING CLOSER I DETERMINED THAT THEIR ENDPOINTS DO LINE UP, A SIGN OF MORE THAN RANDOMNESS, AN INDICATION THAT WITH THE PROPER ADJUSTMENT OF THE COUNTING BEHIND THE ARRAY THESE LINES COULD FORM A FAMILY OF SPANNING DIAGONALS FROM THE HYPOTENUSE TO THE WEST EDGE.

JOTTING DOWN THE NUMBERS THAT THESE DOTS REPRESENT, I NOTICED THAT THE BIGGEST LINE, OF 5 DOTS (LINE D), SHARES THOSE 5 VALUES, IN

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

ORDER, WITH THE LIST OF VALUES FOR  $4x^2 + 2x + 17$ , THE PARABOLA I HAD JUST INTRODUCED IN THE DISCUSSION OF JUT=7, THE FIVE DOTS HERE, HOWEVER, CORRESPONDED TO FIVE CONSECUTIVE VALUES OF  $4x^2 + 2x + 17$  WHERE  $x$  IS NEGATIVE. SHRUGGING THIS OFF AS INDICATING MY LINE OF 5 DOTS IS A STRAIGHT VARIATION OF  $4x^2 + 2x + 17$  ON THE JUT=8 ARRAY, I DECIDED TO LOOK FOR ANY LARGER LINES PARALLEL TO THE 5-DOT LINE. SINCE MY GRAPH WASN'T VERY EXTENSIVE, THERE WASN'T MUCH OUT TO THE RIGHT TO WORK WITH, JUST A PAIR OF DOTS WAY ON THE RIGHT THAT COULD BE THE START OF A LINE GOING SOUTHEAST (FIGURE 114, LINE E). JOTTING THEIR NUMERICAL VALUES DOWN, I STARTED EXTRAPOLATING THEM FORWARD AND BACKWARD (BASED ON THE RATE OF GROWTH IN THE FIRST SMALL PARALLEL LINES, INCLUDING THE ONE WITH 5 DOTS) TO SEE HOW MANY PRIMES THEY WOULD LEAD TO, AND THUS IF THEY WERE PART OF A SIMILAR PARALLEL LINE.

ALL TOLD, 40 STRAIGHT VALUES OF  $x$  GAVE PRIME RESULTS, FROM -19 THROUGH 20, AND THE FORMULA IS  $4x^2 - 2x + 41$ .

BEFORE I EVEN GOT TO DERIVE THE FORMULA, THOUGH, I FIRST WAS EXCITED TO FIND SUCH A BIG GENERATOR BUT THEN ALMOST IMMEDIATELY NOTICED SOMETHING FISHY -- THE HIGHEST PRIME GENERATED IS 1601, ALSO NOTICED THE HIGHEST PRIME GENERATED BY THE REIGNING CHAMP,  $x^2 + x + 41$ . LOOKING CLOSER NOW AT THE NUMBERS IN  $4x^2 - 2x + 41$  IT HIT ME ALL AT ONCE -- THEY ARE THE SAME EXACT NUMBERS AS THOSE GIVEN BY  $x^2 + x + 41$ . ONLY THE PRESENTATION VARIES.

WHILE  $x^2 + x + 41$  GIVES THE 40 PRIMES IN ONE SEQUENCE STARTING WITH 41, 43, 47, 53, 61, 71, 83, ETC., AS  $x$  CLIMBS FROM ZERO ON UP TO 39,  $4x^2 - 2x + 41$  GIVES THEM IN TWO SEQUENCES. FOR VALUES OF  $x$  GREATER THAN ZERO,  $4x^2 - 2x + 41$  CLIMBS FROM 43 TO 53 TO 71 AND SO ON, GIVING EVERY OTHER PRIME, WHILE NEGATIVE  $x$ 'S GIVE THE OTHER HALF OF THE SET OF PRIMES. TO SHOW IT ANOTHER WAY, WITH  $x^2 + x + 41$  41 IS GIVEN BY  $x = 0$ , 43 BY  $x = 1$ , 47 BY  $x = 2$ , 53 BY  $x = 3$ , AND SO ON. FOR  $x^2 - 2x + 41$ , 41 IS GIVEN BY  $x = 0$ , 43 BY  $x = 1$ , 47 BY  $x = -1$ , 53 BY  $x = 2$ , 61 BY  $x = -2$ , AND SO ON, ALTERNATING BACK AND FORTH FROM POSITIVE TO NEGATIVE.

WHAT'S THE NET RESULT OF ALL THIS? WELL, IT WOULD SEEM THAT THERE CAN BE MORE THAN ONE FORMULA GENERATING THE SAME SET OF PRIMES.

WITH THIS IN MIND I TOOK ANOTHER LOOK AT THE LINE WITH 5 DOTS (FIGURE 114, LINE D). (ACTUALLY, THIS LINE IN THE CONTEXT OF JUT=8 IS  $4x^2 - 2x + 17$  WHEREAS IN THE CONTEXT OF JUT=7 THE SAME SEQUENCE FORMED A PARABOLA WITH FORMULA  $4x^2 + 2x + 17$ .) IS  $4x^2 - 2x + 17$  REALLY ANOTHER OLD FRIEND IN DISGUISE? SURE ENOUGH, IT'S  $x^2 + x + 17$ .

AND, OF COURSE, THE TWO SMALLER LINES PARALLEL TO  $4x^2 - 2x + 17$  ARE  $x^2 + x + 5$  AND  $x^2 + x + 11$  ANALOGUES:

$$\begin{aligned} 4x^2 - 2x + 5 \\ 4x^2 - 2x + 11 \end{aligned}$$

(FIGURE 114, LINES B AND C RESPECTIVELY).

PERHAPS, AS WE PROCEEDED, IT WILL TURN OUT THAT OTHER FORMULAS

WHICH GENERATE PRIMES WITH NEGATIVE X'S ALSO POSSESS COMPANION FORMULAS WHICH GENERATE THE SAME PRIMES BUT WITHOUT NEGATIVE X'S.

20.

### STILL LARGER JUTS

A JUT=9 TOP-1 ARRAY DOESN'T YIELD MUCH OF ANYTHING, AT LEAST DURING A PRELIMINARY PLOTTING. THERE IS A TENDENCY TOWARD SOUTHEASTERLY LINES OF DOTS MORE WIDELY SPACED THAN USUAL. ONE NOTEWORTHY INSTANCE OF THESE IS ELEVEN DOTS LONG ON THE ARRAY. ITS FORMULA IS  $18x^2 - 6x + 19$  AND ALTOGETHER IT GENERATES 18 CONSECUTIVE PRIMES, FOR  $-6 < x < 13$ .

THE JUT-10 TOP-1 ARRAY YIELDS TWO NEW LINES:

$$\begin{aligned} 5x^2 + 5x + 7 & \quad -1 < x < 6 \\ 5x^2 + 5x + 13 & \quad -1 < x < 12 \end{aligned}$$

FIGURE 115.

THE JUT-11 TOP-1 ARRAY DISPLAYS A FEW PARABOLAS, BUT THEY TURN OUT TO BE ALREADY KNOWN  $6x^2 + 6x + C$  FORMULAS. INDEED, THESE SAME FORMULAS GENERATE FIVE PARALLEL STRAIGHT LINES SPANNING THE JUT-12 TOP-1 ARRAY.

SINCE ODD JUTS DIDN'T SEEM TO BE PANNING OUT, FROM THIS POINT ON I ONLY CONCENTRATED ON EVEN JUTS WHILE PLOTTING DOTS.

125  
4

JUT-14 TOP-1 DIVULGES TWO MORE NEW LINES:

$$\begin{aligned} 7x^2 + 7x + 5 & \quad -1 < x < 4 \\ 7x^2 + 7x + 17 & \quad -1 < x < 16 \end{aligned}$$

FIGURE 116.

JUT-16 TOP-1 HAS "HALF-DIAGONALS" THAT ONLY REACH HALFWAY TO THE WEST EDGE (SEE FIGURE 117). BY CHANGING THE TOP ROW OF THE ARRAY TO TWO SPOTS, THE HALF-LINES ARE STRETCHED THE REST OF THE WAY ACROSS (SEE FIGURE 118).

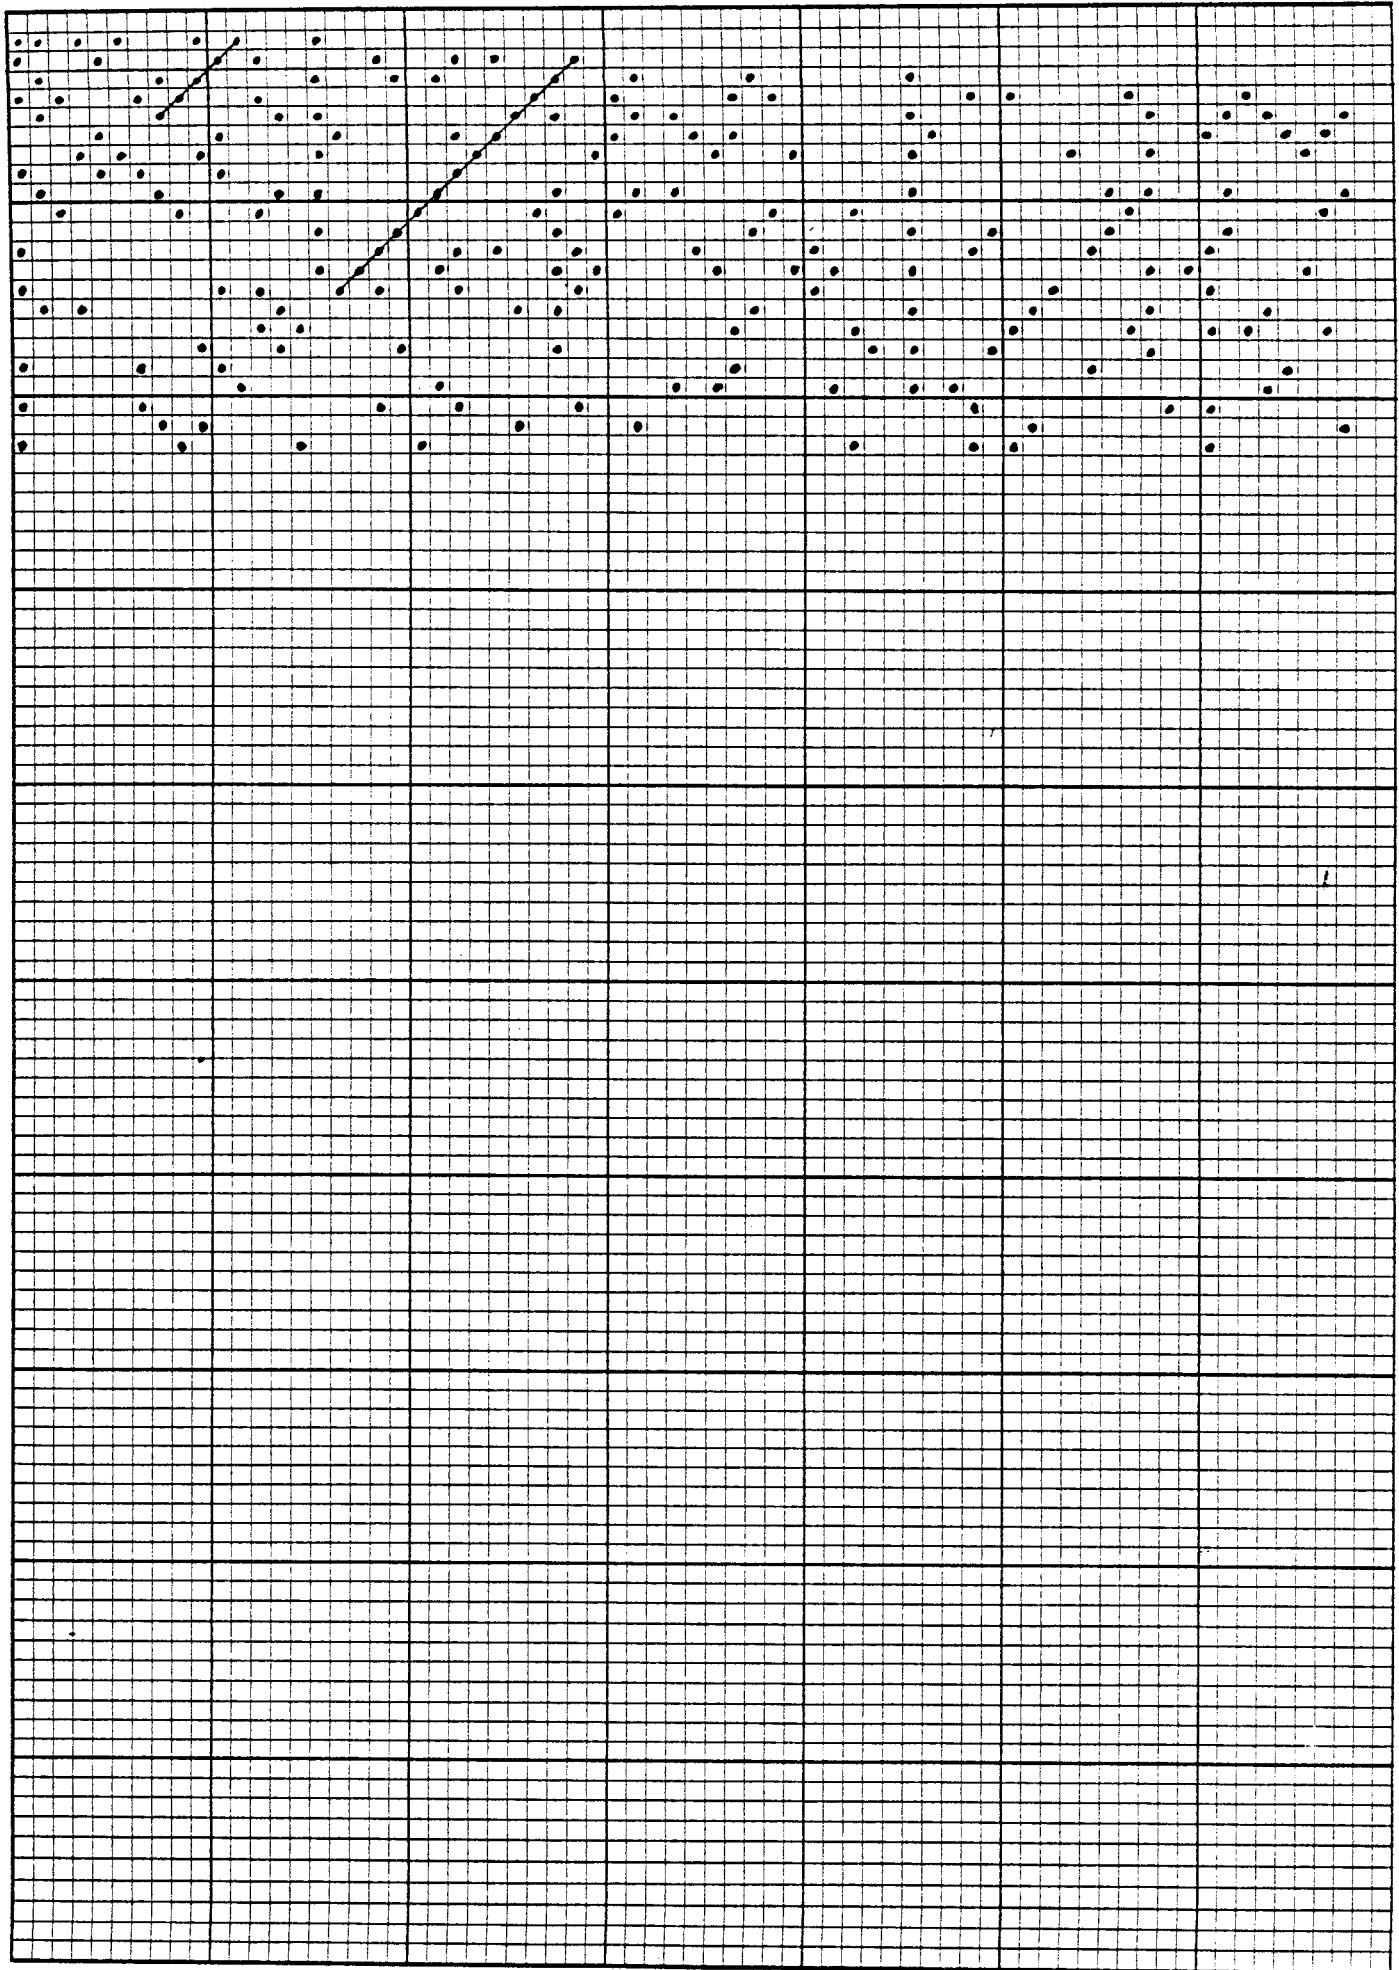

UNIQUE TO JUT-16 TOP-2 IS THAT VERTICAL COLUMNS 1 AND 2 ARE DEVOID OF DOTS, SO THE EFFECTIVE WEST EDGE IS COLUMN 3. COLUMN-1 SPOTS REPRESENT PRODUCTS OF FORM  $(2n - 3)(4n - 5)$ , WHERE N IS ARRAY-ROW-NUMBER, WHILE COLUMN-2 SPOTS REPRESENT EVEN NUMBERS.

BESIDES THE TWO PARALLEL SPANNING DIAGONALS (FIGURE 118, LINES A AND B):

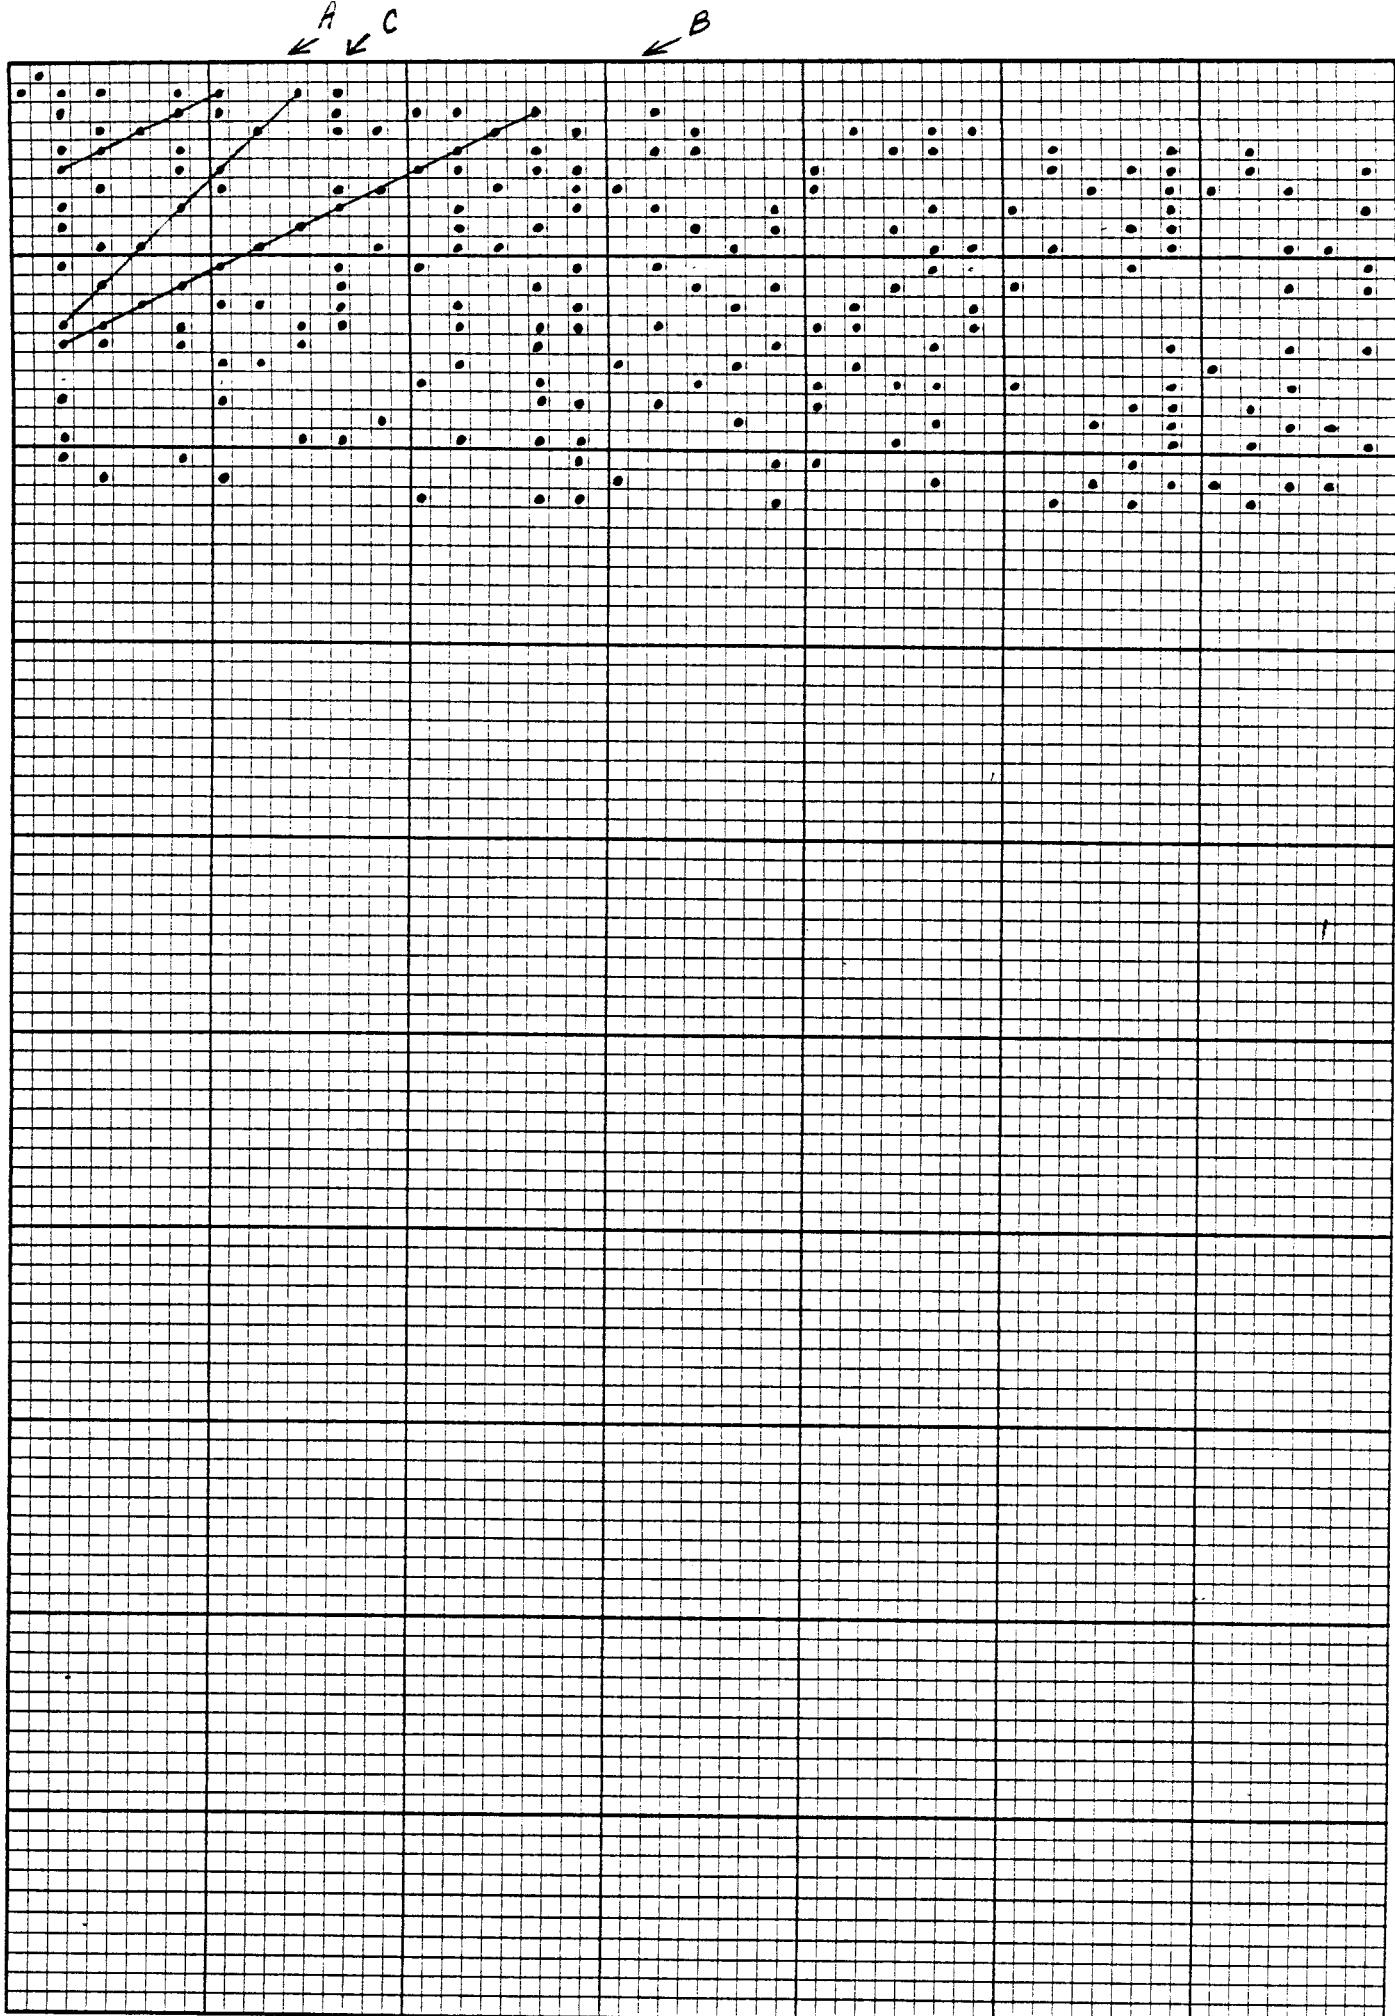

$$\begin{aligned} 8x^2 + 8x + 13 & \quad -1 < x < 5 \\ 8x^2 + 8x + 31 & \quad -1 < x < 14 \end{aligned}$$

FIGURE 119.

THERE IS ANOTHER SPANNING DIAGONAL BUT AT A STEEPER SLOPE (FIGURE 118, LINE C):

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

$$32x^2 - 46x + 31 \quad -7 < x < 8.$$

AT THIS POINT I REALIZED THAT LINES OF FORMULA  $ax^2 + ax + c$  WOULD APPEAR IN ARRAYS OF JUT = 2A, SO I COULD SAVE PLOTTING THE DOTS OF THE ARRAYS FROM HERE ON IN AND SIMPLY JOT DOWN NUMBER SEQUENCES OF FORM  $ax^2 + ax + c$  AND CHECK THEIR MEMBERS FOR PRIMALITY. IF UNBROKEN SEQUENCES OF PRIMES TURNED UP, I COULD PREDICT WHAT ARRAY THEY WOULD BE SPANNING DIAGONALS ON -- JUT = 2A, TOP = 1, IF THE NUMBER OF PRIMES IN THE STRING EQUALS C; TOP = 2, IF THE NUMBER OF PRIMES EQUALS 1/2 (C + 1), AND SO ON FOR FRACTIONAL DIAGONALS.

FOR THAT MATTER I COULD DO THE SAME FOR SEQUENCES BASED ON FORMULAS OF THE FORM  $ax^2 + c$  WHERE A IS EVEN, (ODD VALUES OF A YIELD NUMBER SEQUENCES JUMPING FROM ODD TO EVEN AND BACK, AND SO ARE OUT AS CANDIDATES FOR PRIME LINE GENERATORS.) PREDICTING THE ARRAY FOR  $ax^2 + c$  LINES TURNED OUT TO BE TRICKY BUT EVENTUALLY I GOT THE HANG OF IT: JUT = 2A, TOP = A + 1, FOR "WHOLE" DIAGONALS; TOP = A + 2 FOR "HALF-DIAGONALS", AND SO ON.

BEFORE PROCEEDING ANY FURTHER I SHOULD SAY THAT WORKING STRICTLY WITH NUMBER SEQUENCES AS I DID FROM HERE ON IN HANDICAPPED FINDING NEW LINES IN TWO WAYS. FIRST, I MIGHT MISS LINES IN ARRAYS OF FORM JUT = 2A BY NOT PLOTTING THEIR DOTS; AND SECOND, I WOULD MISS ANY LINES APPEARING IN ARRAYS OF ODD JUT HIGHER THAN ELEVEN, SINCE, AS YOU WILL RECALL, I BEGAN IGNORING SUCH ODD-JUT ARRAYS. ALSO, BY LIMITING THE VALUES OF C TO SMALL PRIMES, USUALLY ONLY UP TO 47, I WAS SHUTTING OUT THE VAST MAJORITY OF POSSIBLE C'S. (IF THE TASK WERE AUTOMATED, MUCH BROADER RANGES OF SEARCH WOULD BECOME FEASIBLE.)

- 128 -

## 21. ALL DONE WITH NUMBERS

THE NEXT VALUE OF A TESTED FOR  $ax^2 + ax + c$  WAS 9, BUT BEFORE DISCUSSING IT I WILL BRIEFLY EXPLAIN WHAT OTHER LINES TURNED UP BY THIS NUMERICAL ANALYSIS WHEN APPLIED RETROSPECTIVELY TO A'S SMALLER THAN 9 FOR  $ax^2 + c$ .

AN ORDINARILY TRIVIAL LINE CONSISTING OF ONLY THREE DOTS GENERATED BY  $2x^2 + 3$  NEVERTHELESS SPANS ARRAY JUT-4 TOP-3. THIS FORMULA FITS IN THE FAMILY OF  $2x^2 + c$  FORMULAS INCLUDING  $2x^2 + 5$ ,  $2x^2 + 11$ , AND  $2x^2 + 29$ .

## TWO FORMULAS IN THE $4x^2 + c$ FAMILY TURN UP:

$$\begin{aligned} 4x^2 + 3 & \quad -1 < x < 3 \\ 4x^2 + 7 & \quad -1 < x < 7. \end{aligned}$$

TOGETHER WITH THE KNOWN  $4x^2 + 4x + c$  TYPE FORMULA,  $4x^2 + 4x + 5$ , THESE FORM A MINI-FAMILY:

$$\begin{aligned} 4x^2 + 3 & \\ 4x^2 + 4x + 5 & \end{aligned}$$

$$4x^2 + 7.$$

LOOKING INTO  $8x^2 + c$ , THREE "HALF-DIAGONALS" TURN UP:

$$\begin{array}{r} 8x^2 + 5 \\ 8x^2 + 11 \\ 8x^2 + 29 \end{array}$$

TAKING INTO ACCOUNT THE TWO  $8x^2 + 8x + c$  FORMULAS DISCUSSED EARLIER AND ARRANGING THESE FIVE FORMULAS IN ORDER, THEN, BY THE NUMBER OF CONSECUTIVE VALUES OF X FOR WHICH THEY GENERATE PRIMES, THEY FORM THE FOLLOWING LIST:

FORMULA	PRIMES IN A ROW
$8x^2 + 5$	3
$8x^2 + 8x + 13$	5
$8x^2 + 8x + 11$	6
$8x^2 + 8x + 31$	14
$8x^2 + 29$	15

FIGURE 120.

RETURNING TO  $9x^2 + 9x + c$ , NO LINES SHOW UP. THIS NEGATIVE "CROP" UNFORTUNATELY INCREASINGLY BECOMES THE RULE AS  $c$  INCREASES. JUST AS DISAPPOINTING IS THE TENDENCY FOR THOSE LINES THAT DO EXIST MERGE TO BE OF MINIMAL LENGTH, BEING HARDLY EVER GREATER THAN 11 NUMBERS LONG. WITH THAT IN MIND, LET'S LOOK AT  $10x^2 + c$ , THE LAST REALLY RICH FIND.

$10x^2 + c$  PRODUCES FOUR PARALLEL STRAIGHT UNBROKEN ARRAY- SPANNING DIAGONAL LINES

$$\begin{array}{r} 10x^2 + 3 \\ 10x^2 + 7 \\ 10x^2 + 13 \\ 10x^2 + 19 \end{array}$$

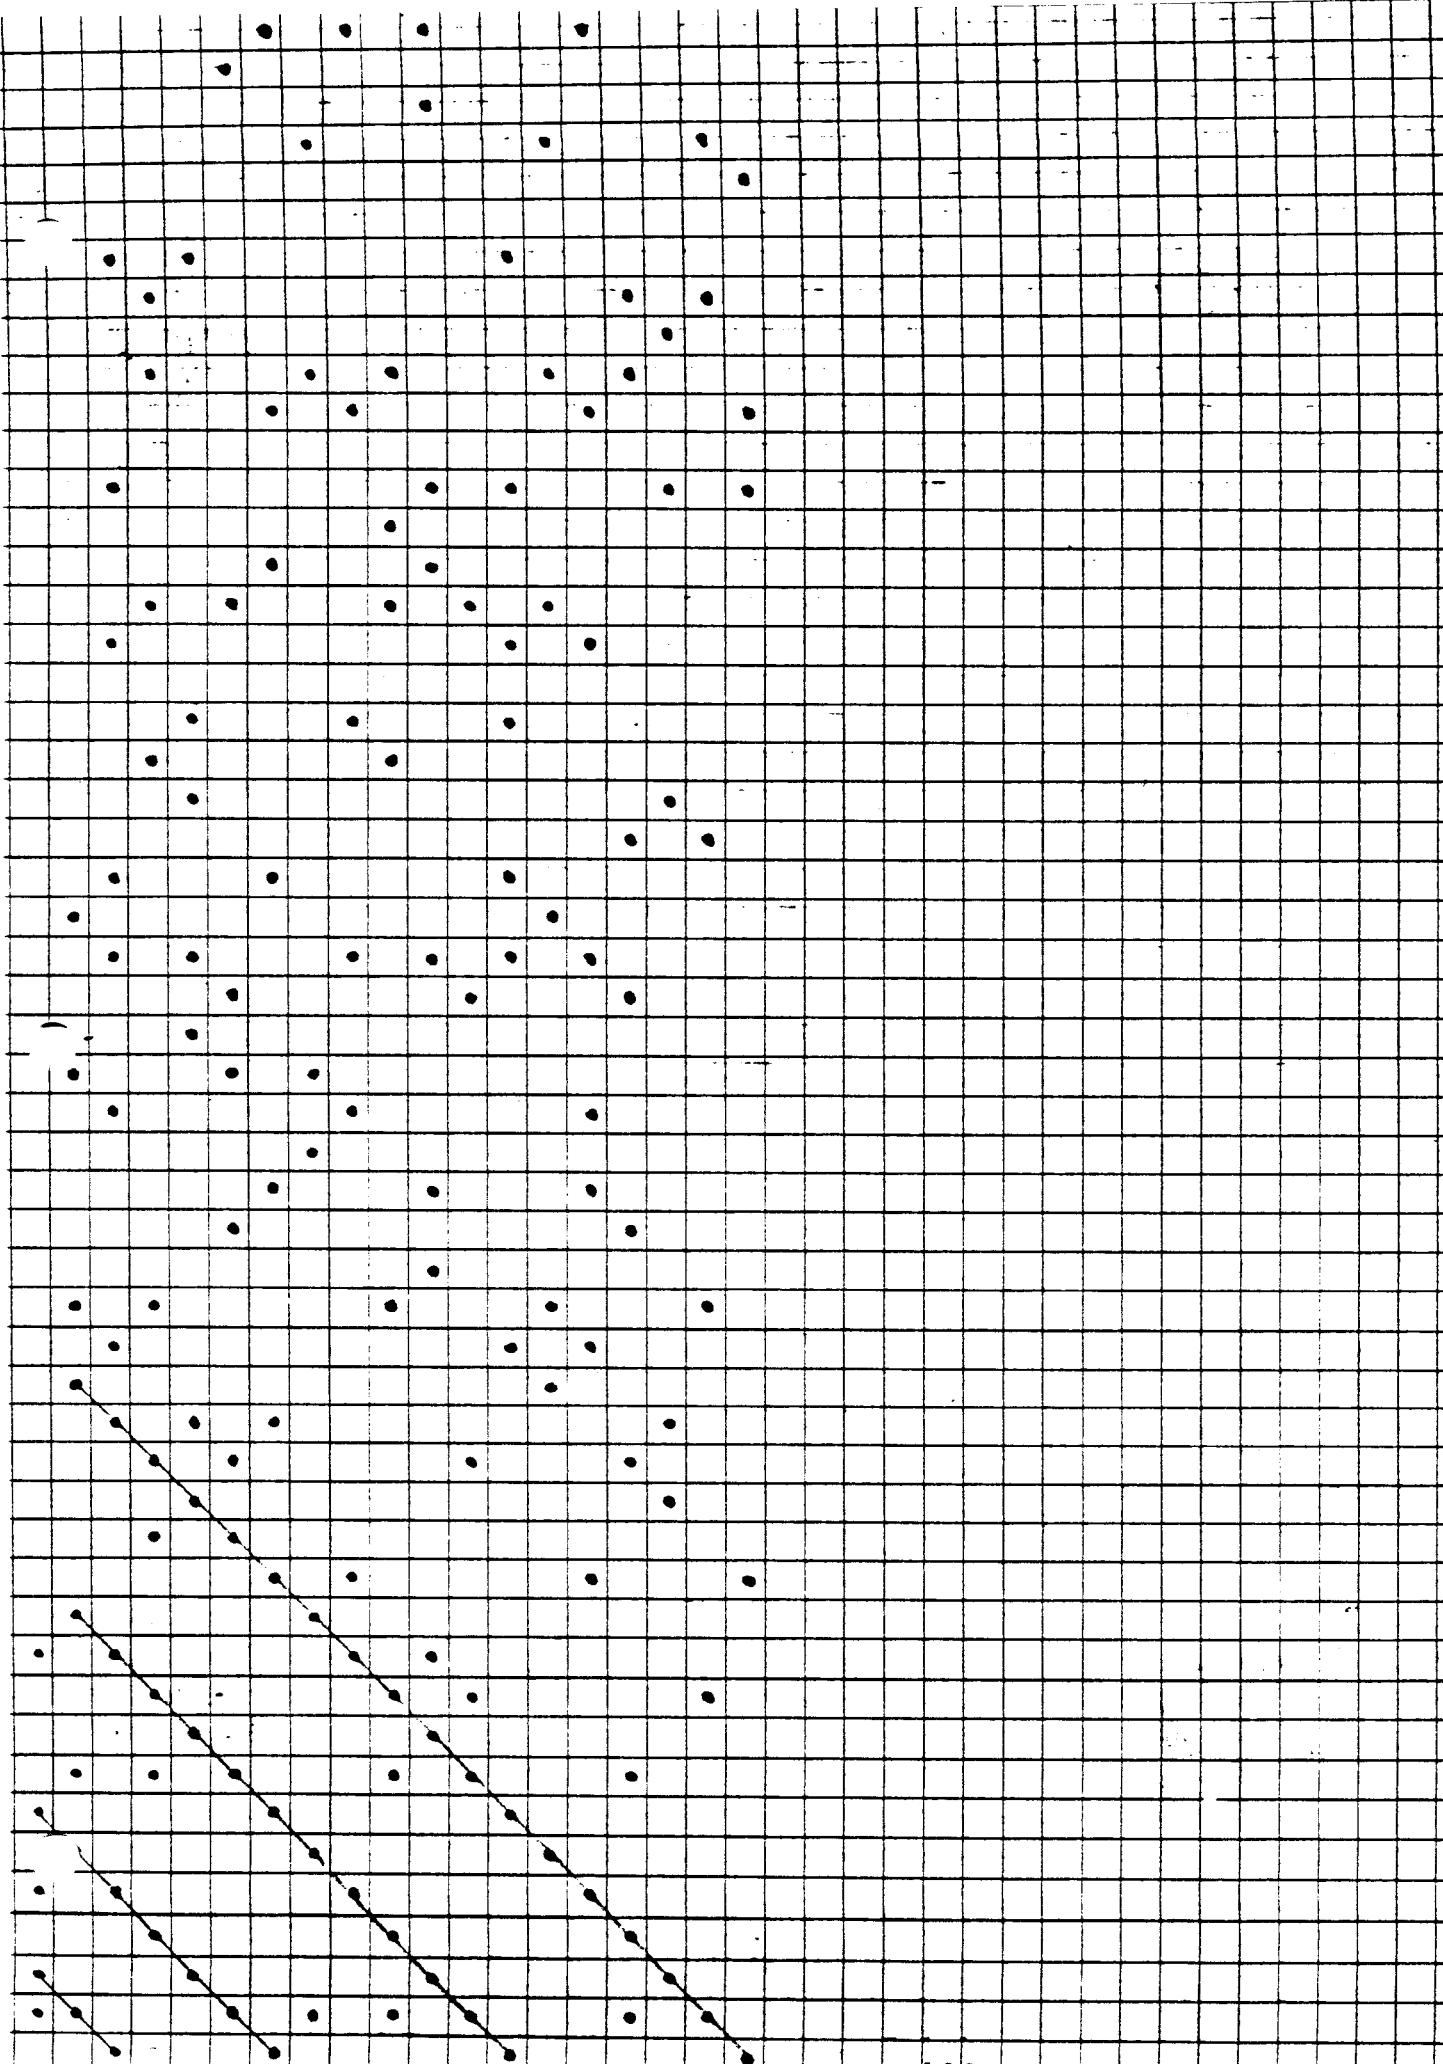

THE ARRAY THAT THESE SHOW UP ON IS JUT-20 (SEE FIGURE 121).

(NOTE: FIGURE 121 ONLY DISPLAYS THE LEFTMOST 53 COLUMNS OF THE ARRAY -- SINCE EACH ROW OF THE ARRAY IS 20 SPOTS LONGER THAN ITS PREDECESSOR, MOST OF THE ARRAY IS TOO WIDE TO FIT HERE. ALSO, ONLY THE TOP 19 ROWS OF THE ARRAY ARE PORTRAYED IN FIGURE 121.)

HERE ARE THE REST OF THE LINES THAT I HAVE FOUND UP TO  $a = 100$ :

FORMULA	PRIMES IN A ROW	JUT	TOP
$11x^2 + 11x + 7$	6	22	1
$12x^2 + 19$	5	24	16
$12x^2 + 31$	8	24	16
$12x^2 + 59$	15	24	16
$13x^2 + 13x + 5$	4	26	1
$13x^2 + 13x + 11$	10	26	1

Figure 121.

14X <sup>2</sup>	+ 3	3	15
14X <sup>2</sup>	+ 5	5	15
14X <sup>2</sup>	+ 13	12*	28
15X <sup>2</sup>	+ 7	6*	30
15X <sup>2</sup>	+ 11	10*	30
15X <sup>2</sup>	+ 13	12*	30
15X <sup>2</sup>	+ 17	16*	30
18X <sup>2</sup>	+ 5	2	36
18X <sup>2</sup>	+ 11	4	36
18X <sup>2</sup>	+ 19	10	36
20X <sup>2</sup>	+ 20X + 19	3**	40
20X <sup>2</sup>	+ 20X + 31	6**	40

FIGURE 122.

\* INTERRUPTING COLUMN PRESENT  
 \*\* BARRIER COLUMN (EFFECTIVE WEST EDGE) PRESENT  
 \*\*\* LAST DOT PAST WEST EDGE BY 2 SPOTS

NOTE: FORMULAS GENERATING ONLY 5 OR FEWER STRAIGHT PRIMES ARE COUNTED ONLY IF THEY FORM PART OF A SET OF RELATED GENERATORS WITH THE COEFFICIENT A. GENERATORS WITH A GIVEN COEFFICIENT ARE RELATED IF A PATTERN IS FORMED BY EACH GENERATOR'S VALUE OF C VERSUS THE NUMBER OF PRIMES IN A ROW THEY EACH PRODUCE.  
 SEE FOR EXAMPLE THE THREE  $12X^2 + C$  FORMULAS. THERE THE NUMBER OF PRIMES IN A ROW FOR EACH FORMULA EQUALS  $(C + 1) / 4$ .

ALSO, PRIME SEQUENCES LONGER THAN 5 HAVE BEEN OMITTED WHEN THEY BEAR NO OBVIOUS RELATIONSHIP TO THEIR C.

## 22. LINE SPECIES

THERE ARE SEVERAL SPECIES OF PRIME LINES THAT HAVE TURNED UP SO FAR. THIS DISCUSSION WILL EXPLAIN HOW A LOT OF THE LINES IN THE PRECEDING EXTENSIVE LIST CAME TO BE MEMBERS IN THE LIST. ALONG THE WAY, THE UNFAMILIAR TERMS USED IN THE FOOTNOTES TO THE LIST WILL BEGIN TO TAKE ON MEANING.

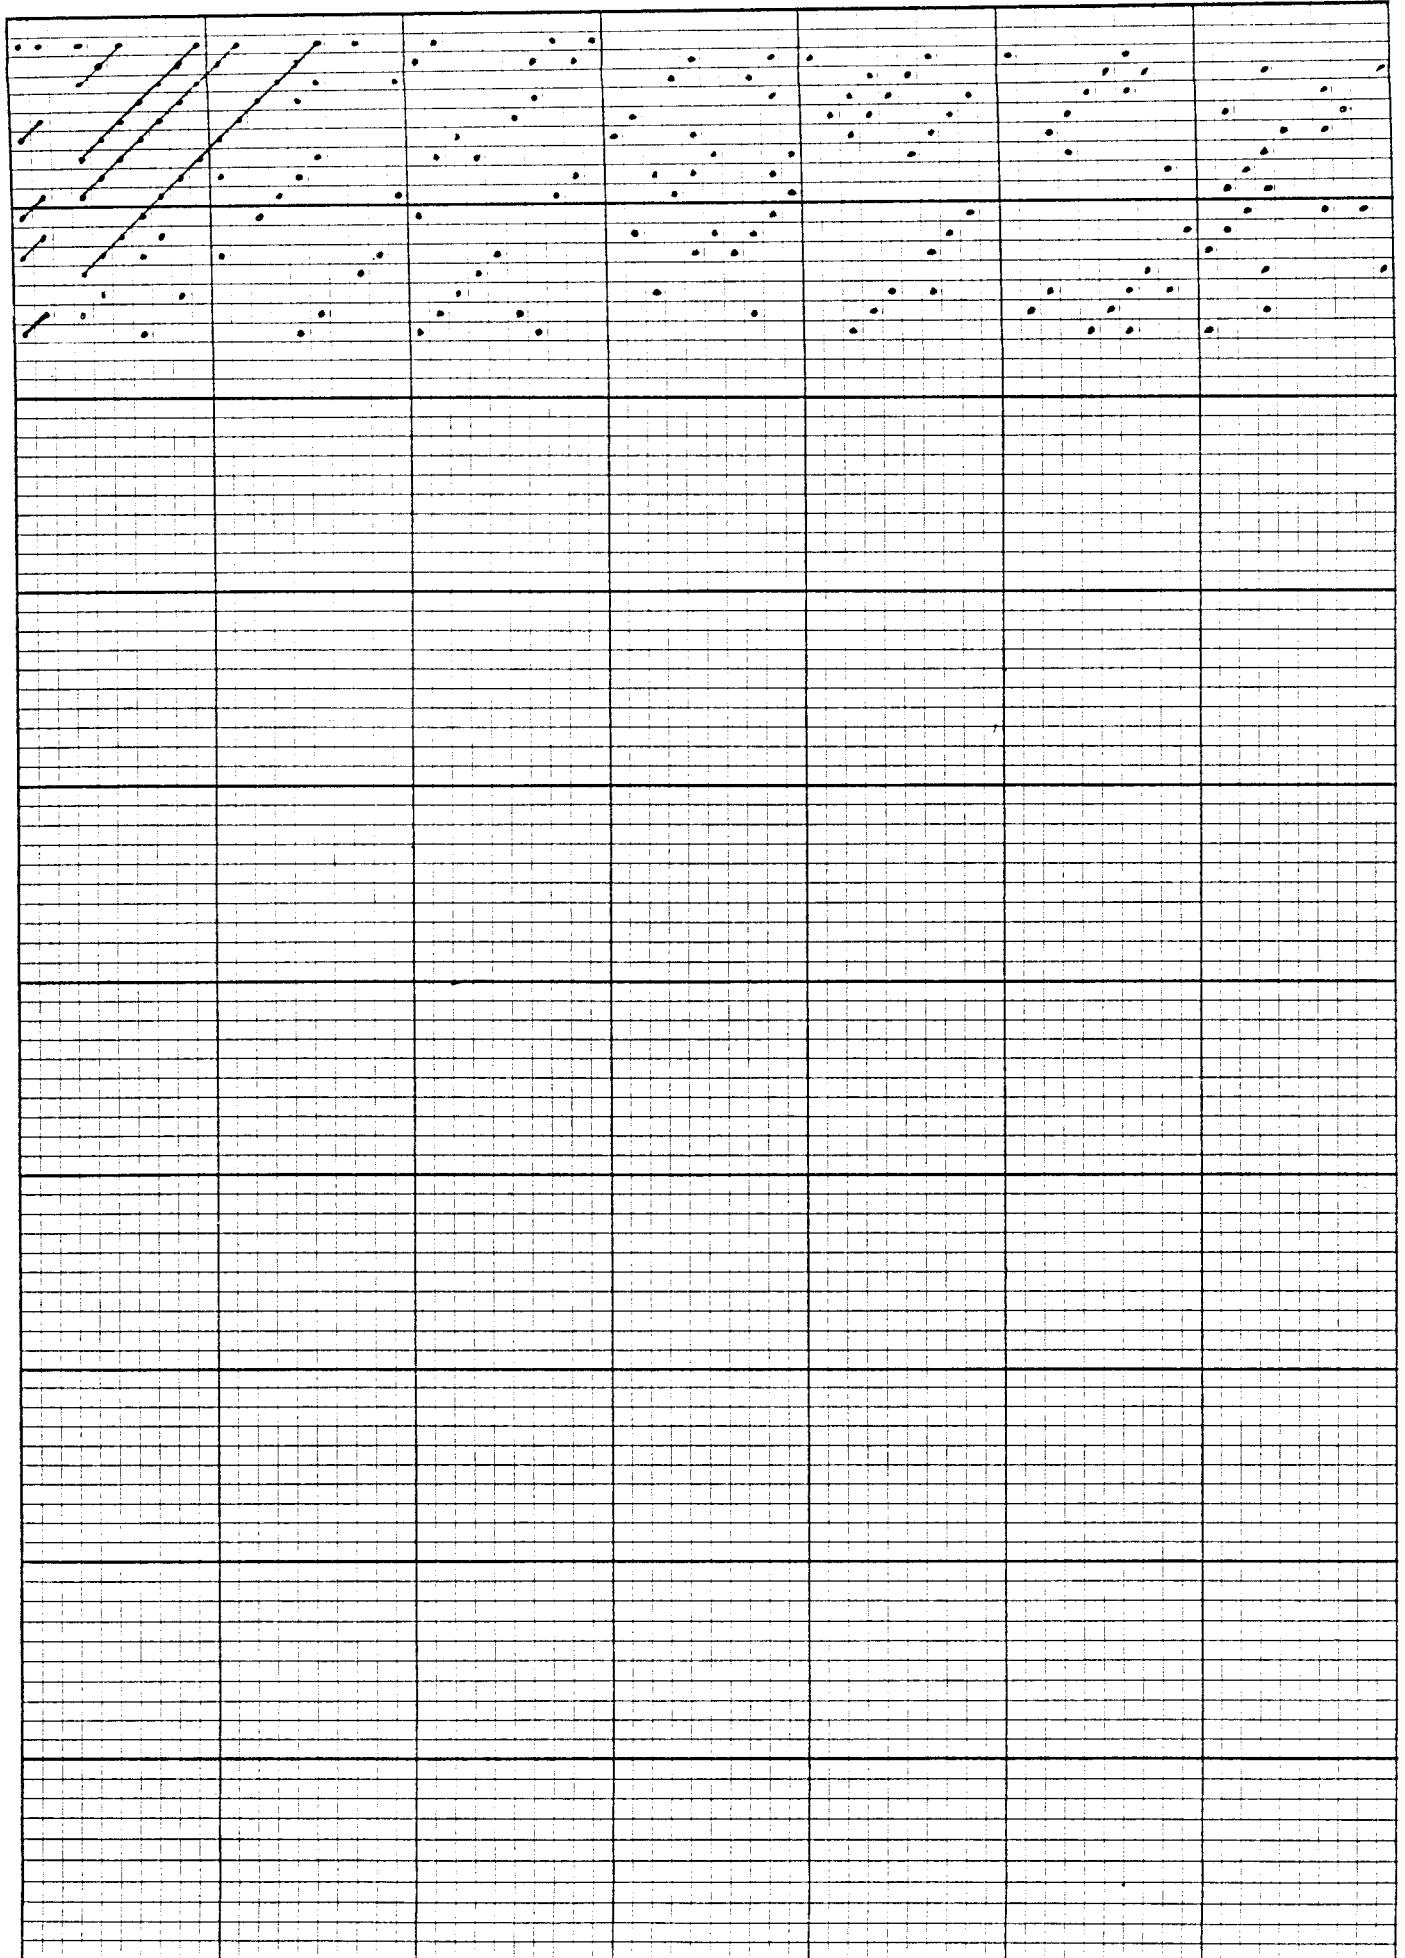

IN GENERAL, INCLUSION IN THE LIST OF PRIME LINES ASSUMES A TRIANGULAR COUNTING ARRAY AS THE CONTEXT. SUCH AN ARRAY HAS A TOP ROW OF SOME NUMBER OF SPOTS AND EACH SUBSEQUENT ROW JUTS OUT TO THE RIGHT BY SOME CONSTANT QUANTITY OF SPOTS. THE LEFT ENDS OF ALL ROWS ARE VERTICALLY ALIGNED -- IN OTHER WORDS, THERE IS NO JUTTING ON THE LEFT. COUNTING IS OF COURSE LEFT TO RIGHT. A SPOT REPRESENTING A PRIME NUMBER IS MARKED WITH A DOT, WHILE ALL OTHER SPOTS ARE LEFT VACANT.

GIVEN SUCH A TRIANGULAR ARRAY, A PRIME LINE IS A DIAGONAL LINE OF DOTS ON THE ARRAY SLANTING FROM NORTHEAST TO SOUTHWEST AND SPANNING ACROSS THE ARRAY FROM THE UPPER RIGHT EDGE, OR "HYPOTENUSE", TO THE WEST EDGE. ONE FURTHER RESTRICTION ON THE DOTS OF A PRIME LINE IS THAT THEY BE EVENLY SPACED ALONG THE DIAGONAL.

INHERENT IN PRIME LINES IS THAT THEY REPRESENT UNBROKEN SEQUENCES OF PRIME NUMBERS. THE SEQUENCES ARE UNBROKEN IN THE SENSE THAT FOR CONSECUTIVE WHOLE VALUES OF X PLUGGED INTO AN EXPRESSION, THE EXPRESSION PRODUCES THESE PRIME NUMBERS. USUALLY MOST BUT NOT ALL OF THE CONSECUTIVELY PRODUCED PRIMES ARE REPRESENTED IN THE STRING OF DOTTED SPOTS IN A SPANNING DIAGONAL. OFTEN THE FIRST PRIMES IN THE UNBROKEN PROGRESSION ARE NOT IN THE DIAGONAL, WHILE THE DIAGONAL CONTAINS THE REST OF THEM, THE LAST DOT ON THE DIAGONAL COINCIDING WITH THE LAST PRIME IN THE UNBROKEN PROGRESSION.

THE FIRST SPECIES OF PRIME LINE IS THE IDEAL PRIME LINE. IT HAS ALL OF THE ABOVE CHARACTERISTICS. IN ADDITION, THE LAST DOT IN THE DIAGONAL OF AN IDEAL PRIME LINE IS IN COLUMN 1, THE LEFTMOST COLUMN OF THE ARRAY. FOR AN IDEAL PRIME LINE THAT DOT ALSO REPRESENTS THE LAST PRIME IN THE UNBROKEN PROGRESSION OF PRIMES GENERATING THE LINE. AN EXAMPLE OF AN IDEAL PRIME LINE IS GENERATED BY THE EXPRESSION  $x^2 + x + 41$  ON ARRAY JUT-2 TOP-1.

THE SECOND SPECIES OF PRIME LINE IS THE INTERRUPTED PRIME LINE. SUCH A DIAGONAL HAS ONE NON-PRIME SPOT IN ITS OTHERWISE UNBROKEN STRING OF DOTS. AN INTERESTING PHENOMENON INVOLVING INTERRUPTED PRIME LINES OCCURS WHEN THERE IS MORE THAN ONE PRIME LINE ON AN ARRAY. IF ANY OF THE LINES ON THE ARRAY IS INTERRUPTED, ALL WILL BE. BUT NOT ONLY THAT, ALL OF THE LINES WILL BE INTERRUPTED IN THE SAME COLUMN. WHATEVER COLUMN THAT HAPPENS TO BE, IT CONTAINS NO PRIMES WHATSOEVER. SEE THE FOUR INTERRUPTED DIAGONALS IN FIGURE 123, INTERRUPTED BY COLUMN 3. THESE FOUR PRIME LINES ARE GENERATED BY THE FOUR EXPRESSIONS:

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

$$\begin{aligned} 15x^2 + 15x + 7 \\ 15x^2 + 15x + 11 \\ 15x^2 + 15x + 13 \\ 15x^2 + 15x + 17. \end{aligned}$$

THE THIRD SPECIES OF PRIME LINE IS THE TRUNCATED PRIME LINE. THESE DIAGONALS ARE NOT ONLY INTERRUPTED BY A COLUMN BUT ARE HALTED BY IT AS WELL. AGAIN, WHEN MORE THAN ONE PRIME LINE IS PRESENT IN AN ARRAY, IF ANY DIAGONAL MEETS SUCH A BARRIER COLUMN, ALL DIAGONALS ARE TRUNCATED BY THAT COLUMN. EXAMPLES ARE

$$\begin{aligned} 30x^2 + 30x + 11 \\ 30x^2 + 30x + 13 \\ \text{AND } 30x^2 + 30x + 19 \end{aligned}$$

ON THE ARRAY WITH JUT-60 AND TOP-1. THE BARRIER COLUMN IS COLUMN 7. (SEE FIGURE 124.)

THE FOURTH SPECIES OF PRIME LINE IS THE STRETCHED PRIME LINE. STRETCHED PRIME LINES ARE FORMED FROM FRACTIONAL DIAGONALS BY STRETCHING THEM THE REST OF THE WAY ACROSS THE ARRAY TO THE WEST EDGE. THE STRETCHING IS ACCOMPLISHED BY ADJUSTING THE LENGTH OF THE TOP ROW OF THE ARRAY, GIVEN THAT IDEALLY FOR  $ax^2 + ax + c$

TYPE LINES THE TOP HAS ONE SPOT AND FOR  $ax^2 + c$  TYPE LINES THE TOP HAS  $a + 1$  SPOTS, TO STRETCH "HALF-DIAGONALS" WE MAKE THE TOP ROW 2 SPOTS OR  $a + 2$  SPOTS RESPECTIVELY, FOR "THIRD-DIAGONALS" WE MAKE THE TOP 3 SPOTS OR  $a + 3$  SPOTS RESPECTIVELY,

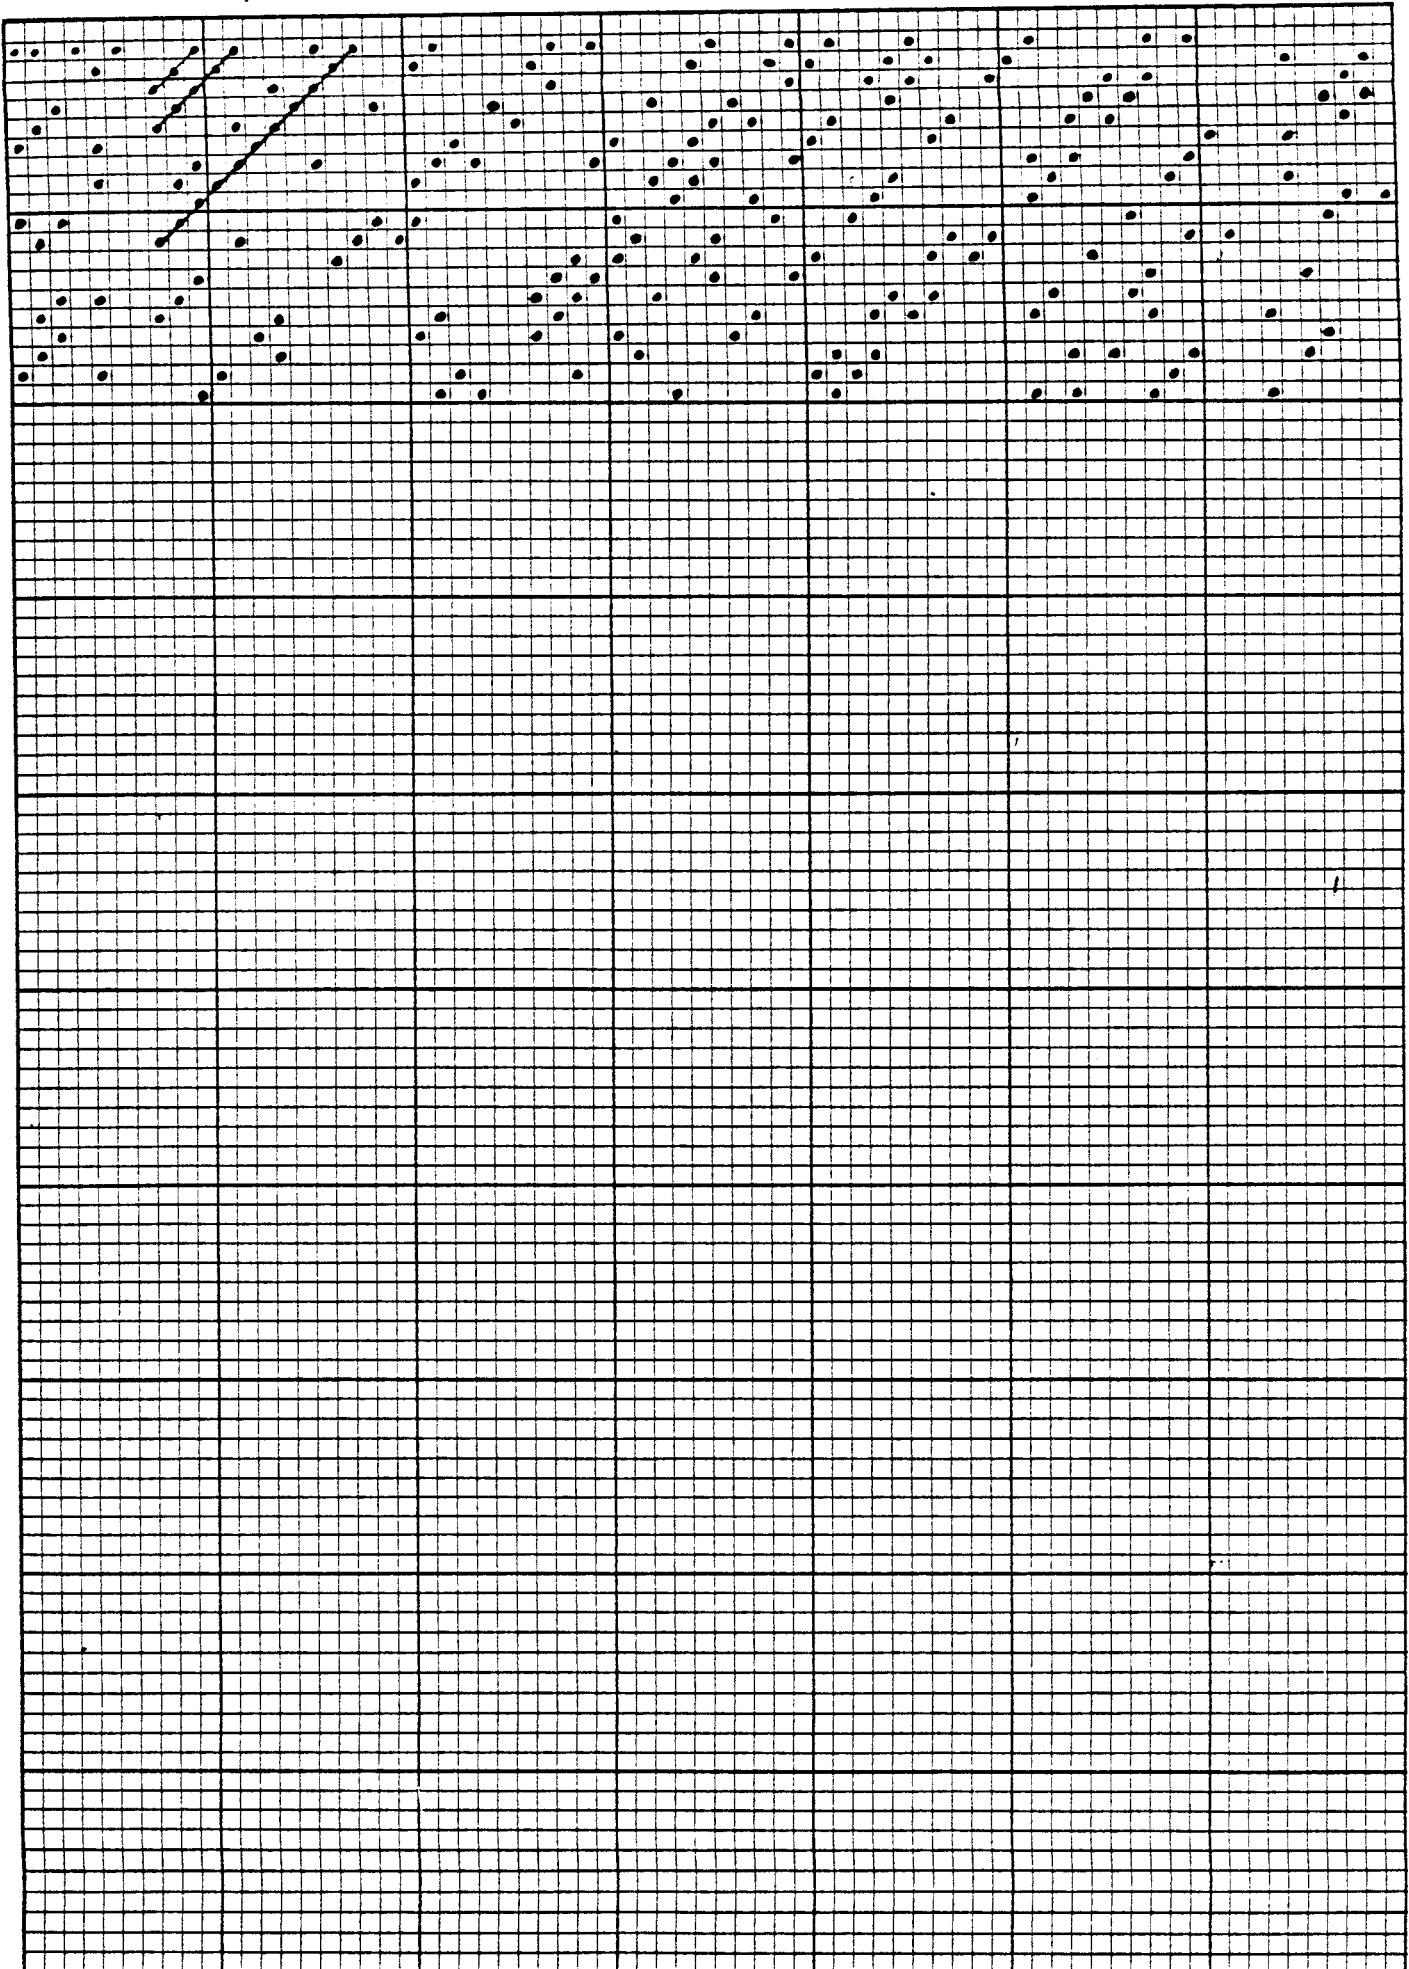

FOR "QUARTER-DIAGONALS" WE MAKE THE TOP 4 SPOTS OR  $a + 4$  SPOTS RESPECTIVELY, AND SO ON. FOR AN ARRAY WITH MORE THAN ONE PARALLEL FRACTIONAL DIAGONAL, STRETCHING AFFECTS EACH SUCH DIAGONAL IN THE SAME WAY. FOR EXAMPLE, THE THREE "QUARTER-DIAGONALS" ON ARRAY JUT-24 TOP-13 GENERATED BY

$$\begin{aligned} 12x^2 + 19 \\ 12x^2 + 31 \\ \text{AND } 12x^2 + 59 \end{aligned}$$

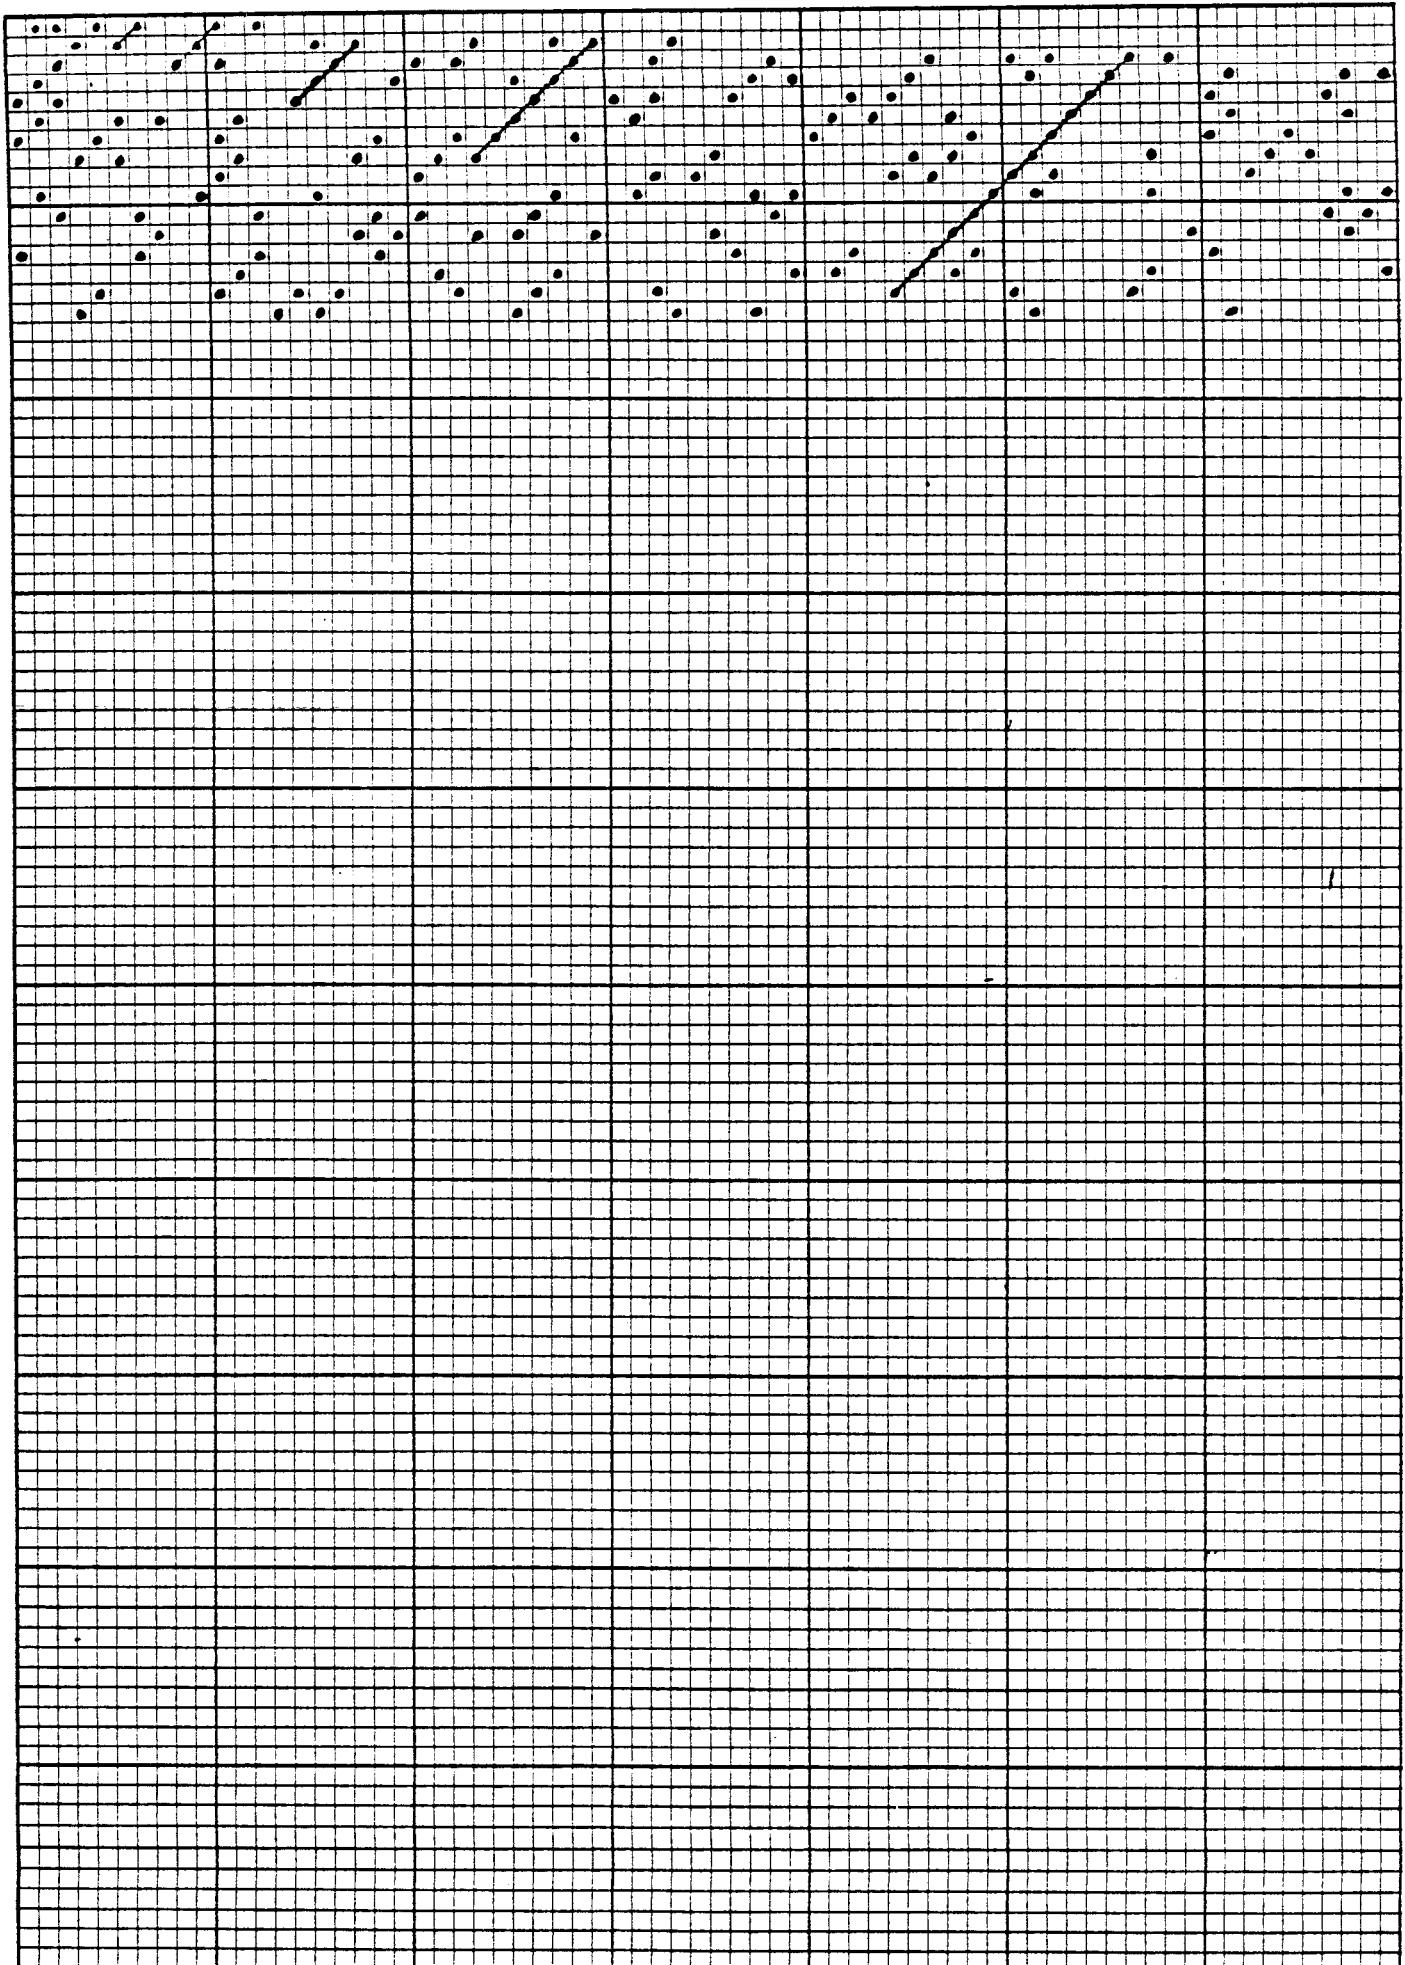

ARE STRETCHED THE REST OF THE WAY TO THE WEST EDGE BY MAKING THE TOP ROW 16 SPOTS LONG (SEE FIGURES 125 AND 126).

THE FIFTH SPECIES OF PRIME LINE IS THE OVERSTRETCHED PRIME LINE. THESE ARE STRETCHED PRIME LINES WHICH NOT ONLY SPAN TO THE WEST EDGE BUT WOULD EXTEND ONE DOT PAST THE WEST EDGE IF SUCH EXPANSION WERE PERMITTED. FOR AN OVERSTRETCHED PRIME LINE, THE NEXT-TO-LAST NUMBER IN THE UNBROKEN SEQUENCE OF PRIMES ENDS UP BEING REPRESENTED BY THE LAST DOT ON THE SPANNING DIAGONAL. AN EXAMPLE OF AN OVERSTRETCHED PRIME LINE IS GENERATED BY  $25x^2 + 25x + 47$  ON ARRAY JUT-50 TOP-3 (SEE FIGURE 127).

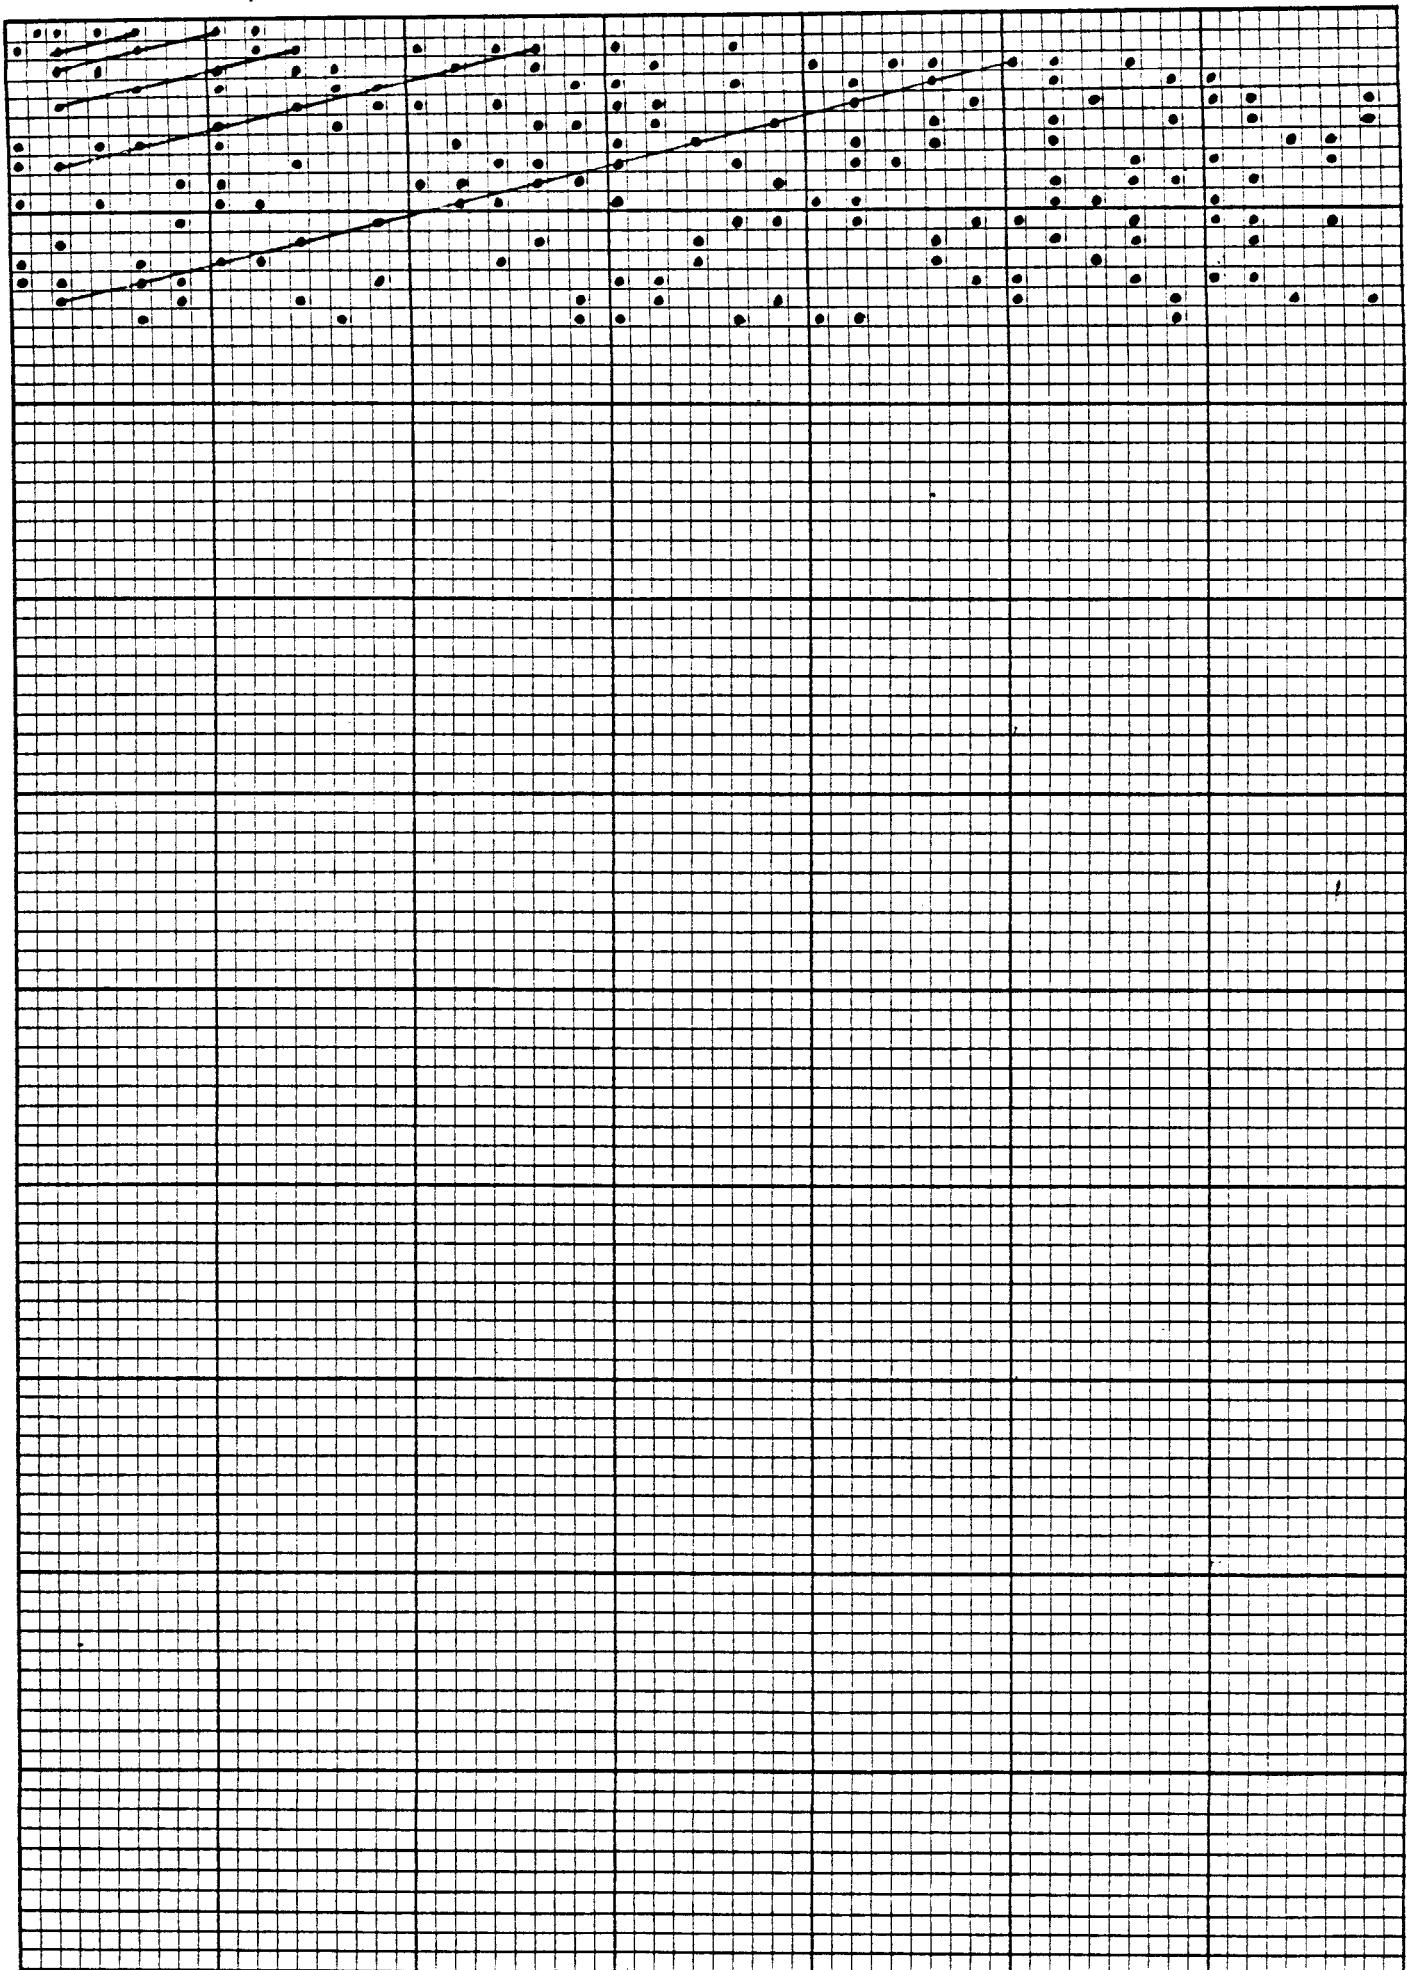

FINALLY, THE SIXTH SPECIES OF PRIME LINE SO FAR ENCOUNTERED IS THE TRUNCATED, STRETCHED OR UNDERSTRETCHED PRIME LINE. SUCH A LINE HAS BEEN STRETCHED AS FAR AS POSSIBLE TOWARD THE WEST EDGE BUT WITHOUT GOING "PAST" IT, AND HAS COME UP AGAINST A BARRIER COLUMN. WHEN A SET OF PARALLEL FRACTIONAL PRIME LINES ON AN ARRAY IS

CITADEL® NO. 642 - CROSS SECTION - 10 SQUARES TO INCH

**STRETCHED AND ANY OF THEM HITS SUCH A BARRIER, ALL WILL HIT IT.  
AN EXAMPLE OF THIS IS THE BEHAVIOR OF THE "HALF-DIAGONALS" GENERATED BY**

$$\begin{aligned} & 24X^2 + 24X + 13 \\ & 24X^2 + 24X + 19 \\ & \text{AND} \\ & 24X^2 + 24X + 23 \end{aligned}$$

**WHEN STRETCHED BY ARRAY JUT-48 TOP-2. THE BARRIER COLUMN IS  
COLUMN 6 (SEE FIGURE 128).**

Figure 128 shows the first 100 terms of the sequence generated by the three polynomials above. The first 100 terms of the sequence are plotted against the index of the term. The plot shows a series of points that form a pattern that repeats every 24 terms. The points are clustered around a horizontal line, which represents the barrier column. The points are also clustered around a vertical line, which represents the barrier row.

The plot shows that any term in the sequence that falls on the barrier column or barrier row will hit the barrier. This is because the barrier column and barrier row are defined by the same set of rules that generate the sequence. The barrier column is defined by the equation  $X = 6$ , and the barrier row is defined by the equation  $X = 13$ . The sequence is generated by the equation  $X = 24X^2 + 24X + 13$ .

The plot also shows that the sequence is periodic with a period of 24. This is because the sequence is generated by a polynomial of degree 2, and the period of a polynomial of degree 2 is always a divisor of 24. The plot also shows that the sequence is symmetric about the center point (12, 12), which is the midpoint of the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

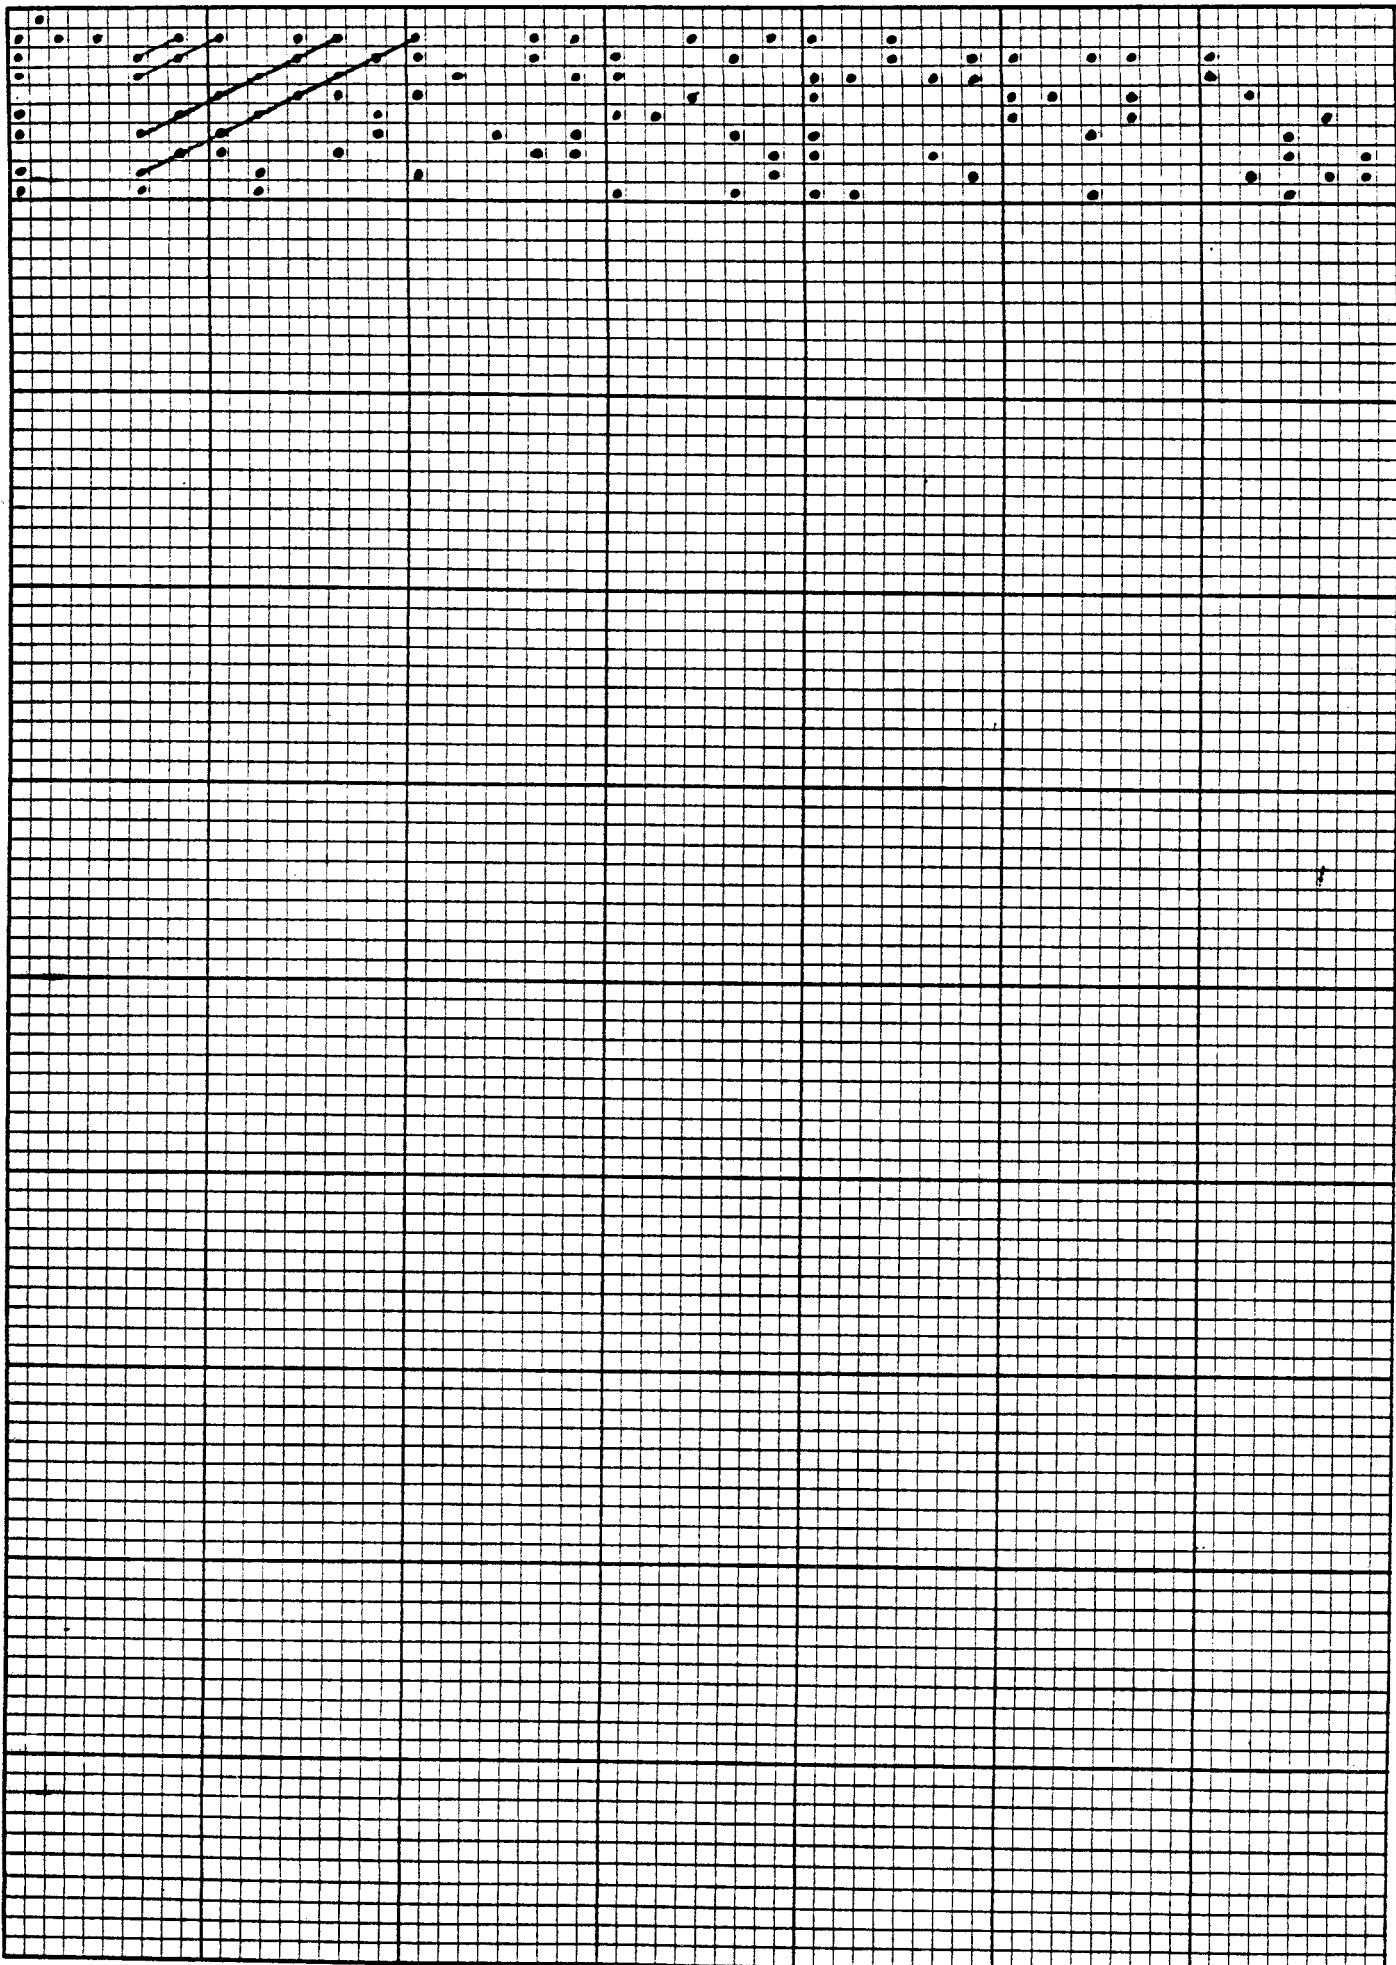

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.

The plot also shows that the sequence is not random. The points are clustered around the barrier column and barrier row, and the points are also clustered around the barrier column and barrier row. This is because the sequence is generated by a polynomial of degree 2, and the points are clustered around the barrier column and barrier row.
